ABSTRACT

Analyzing initiating event rates is important because it indicates performance among plants and also provides inputs to several U.S. Nuclear Regulatory Commission (NRC) risk-informed regulatory activities. This report presents an analysis of initiating event frequencies at U.S. commercial nuclear power plants since each plant's low-power license date. The evaluation is based on the operating experience from fiscal year 1988 through 2013 as reported in licensee event reports. Engineers with nuclear power plant experience staff reviewed each event report since the last update to this report for the presence of valid scrams or reactor trips at power. To be included in the study, an event had to meet all of the following criteria: includes an unplanned reactor trip (not a scheduled reactor trip on the daily operations schedule), sequence of events starts when reactor is critical and at or above the point of adding heat, occurs at a U.S. commercial nuclear power plant (excluding Fort St. Vrain and LaCrosse), and is reported by a licensee event report. This report displays occurrence rates (baseline frequencies) for the categories of initiating events that contribute to the NRC's Industry Trends Program. Sixteen initiating event groupings are trended and displayed. Initiators are plotted separately for initiating events with different occurrence rates for boiling water reactors and pressurized water reactors. p-values are given for the possible presence of a trend over the most recent 10 years.

PWR pressurized water reactor

Initiating Event Rates at U.S. Nuclear Power Plants 1988–2013

An initiating event is an unplanned event that occurs while a nuclear power plant is in critical operation and requires that plant to shut down to achieve a stable state. Analyzing initiating event rates is important because it indicates performance among plants and also provides inputs to several U.S. Nuclear Regulatory Commission (NRC) risk-informed regulatory activities (such as plant inspections of risk-important systems) and NRC staff technical reviews of proposed license amendments, including risk-informed applications. The objectives of the initiating event study are to

1. Provide revised, historical frequencies for the occurrence of initiating events in U.S. nuclear power plants
2. Compare these estimates based on operating experience to estimates used in probabilistic risk assessments, individual plant examinations, and other regulatory issues
3. Review the operating data from an engineering perspective to determine trends and patterns of plant performance on a plant type [i.e., pressurized water reactor (PWR) or boiling water reactor (BWR)], plant-specific, and industry-wide basis.

This report presents an analysis of initiating event frequencies at U.S. commercial nuclear power plants since each plant's low-power license date. The evaluation is based on the operating experience from fiscal year 1988 through 201, as reported in licensee event reports (LERs). This is the latest update to NUREG/CR-5750 (Reference 1), updating data, frequency estimates, trends, and figures.

To determine initiating event rates, engineers with nuclear power plant experience staff reviewed each LER since the last update to this report for the presence of valid scrams or reactor trips at power. To be included in this study, an event had to meet all of the following criteria:

- Includes an unplanned reactor trip (not a scheduled reactor trip on the daily operations schedule)
- Sequence of events starts when reactor is critical and at or above the point of adding heat
- Occurs at a U.S. commercial nuclear power plant (excluding Fort St. Vrain and LaCrosse)
- Be reported by an LER.

Each reactor trip event was then reviewed for the following information:

- All occurrences of risk-significant events in the reactor trip sequence that could impact the ability to remove reactor decay heat
- The first event in the sequence of events that causes or leads to the unplanned, automatic or manual reactor trip
- The occurrence of a manual reactor trip.

The information was collected into two groups or data sets:

1. The initial plant fault group—contains the reactor trip event initiator for each reactor trip
2. The functional impact group—contains one or more risk-significant events that occur during each reactor trip.

1. BASELINE FREQUENCIES

This report displays occurrence rates (baseline frequencies) for the categories of initiating events that contribute to the NRC's [Industry Trends \(ITP\)](#) and other programs. Sixteen initiating event groupings are trended and displayed. BWR and PWR initiators are plotted separately for initiating events with different occurrence rates for the two plant types. Each figure is annotated with the p-value^a for the possible presence of a trend over the most recent 10 years.

In accordance with the particular starting years have been identified for each of these initiating events for baseline periods during which the initiating event frequencies are approximately constant.

The maximum likelihood estimate (the total number of events divided by the total number of reactor critical years) is plotted for each occurrence rate in each fiscal year. For each baseline period, the maximum likelihood estimate is the total event count (summed over the calendar years in the baseline period), divided by the corresponding sum of reactor critical years. In addition, the mean of the distribution used in the ITP (Jeffreys or empirical Bayes) is presented in **Error! Reference source not found.**

The limits in each year are simple 5th and 95th percent confidence bounds. For the baseline period, the horizontal limits are computed from the predictive distribution (Poisson-Gamma) that describes the number of events that would be expected in a following year based on the number of events (plus 0.5), the occurrence time in the baseline period, and the exposure time in the following year. The predictive bounds for the baseline period assume that the occurrences are following a constant rate for that period and the future. Comparing future data with those bounds helps to determine whether the data are changing.

Initiating events occur infrequently in nuclear power plants. Among the categories currently trended on the [initiating event web page](#), six have prediction limits on the counts of at least 6, while the count limits for the remaining 10 initiating events are either 3 events per year or 2 events per year. The IEs in the first category occur more commonly, and are described here as “infrequent,” while the other initiators are sparse. Four of the sparse initiators continue to employ baseline periods that use as much of the U.S. NPP historic data as possible.

New baseline periods ending in 2010 are being sought. For the four very sparse initiators, using all the data is still desirable. The total number of baseline period events for any of these initiators is still less than 5, although the reporting period data time span has increased from 15 years to 23 years.

Treating the other six initiators with prediction limits of 2 or 3 events per year the same as the very sparse initiators results in baseline periods with reasonable properties. That is, the hypothesis of homogeneity between years is not rejected, and significant trends are not seen. These periods are “long,” as with the very sparse initiators. The starting year is not changed while the ending year is moved to 2010.

For the remaining six initiators with relatively high original baseline period prediction limits (greater than 5 events in a future year), moving just the ending year to 2010 results in some baseline periods with significant decreasing trends. Also, for loss of offsite power (LOOP) events, the hypothesis of homogeneous data across years is rejected (the p-value is extremely highly significant). An alternate choice is to preserve the length of the baseline periods for these initiators. The initial choices for baseline periods included sufficient data to characterize performance. Keeping the length of the period as initially

a. Statistical significance is defined in terms of the ‘p-value.’ A p-value is a probability indicating whether to accept or reject the null hypothesis that there is no trend in the data. P-values of less than or equal to 0.05 indicate that we are 95% confident that there is a trend in the data (reject the null hypothesis of no trend.) By convention, we use the “Michelin Guide” scale: p-value < 0.05 (statistically significant), p-value < 0.01 (highly statistically significant); p-value < 0.001 (extremely statistically significant).

established in the Industry Trend Program continues that pattern while using the more current data (2010). This choice works well for all of the IEs except LOOP. The new baseline data are homogenous and do not exhibit a significant trend.

Basing the selection for LOOP on the original baseline period length produces a new period (2003 to 2010) that also fails the qualifications for baseline periods. The data are not homogenous with regard to year, and there is a highly statistically significant decreasing trend. Moreover, a different criterion for selection of the LOOP baseline is appropriate because the original selection was based on when the electrical distribution systems were deregulated (1997), rather than on data needs.

LOOP performance during operational periods varies widely from year to year. The events are often not independent. The probability of a grid or weather related LOOP affecting more than one unit at a multi-unit site is relatively high (the estimate is 0.39; see 2011 LOOP Update). The data have more scatter than the other initiating event categories. The data from 2001 to 2004 typify this scatter, with 2, 0, 12, and 5 events, respectively. On the other hand, there were no LOOP events in 2010, the target ending year of the baseline periods.

In addition to the 2003-2010 period for LOOP, the period from 2002 to 2010 and the period from 2004 to 2010 were considered for the baseline period for LOOP. The longer period had the same problems of highly significant between-year differences and decreasing trend. However, the 2004-2010 period performs better and is now used for detecting trends (see Table 1). The p-value for a test of homogeneity continues to reject the hypothesis, but it is no longer highly statistically significant (0.018). The trend drops below significance (to 0.079), although the goodness-of-fit test for the Poisson regression remains poor (p-value 0.015).

Table 1 summarizes the updated baseline data. It includes the data totals, the upper prediction limit that could be used in an evaluation of short-term trends, and information about representative industry gamma distributions for each initiator frequency.

2. TRENDS

Error! Reference source not found. shows the current 10-year trends for the sixteen IEs being tracked and data for the current year. The Trend column reports the p-value and an indication of increasing or decreasing for statistically significant p-values. The p-value is also shown in each figure. In addition, the current year (201) initiating event count is shown and is compared to its prediction limit (PL).

Previous updates have shown the trend from calendar year (CY) 1988. In this update, the trends are based on data from the most recent 10 years. Plots of the data and trend line follow. The baseline periods and prediction limit bounds are marked. The vertical bounds in each year are confidence bounds. A separate link provides tables of LERs associated with the events and tables of the plotted data.

The trend line plot for partial loss of service water does not show because it drops abruptly from the data value for 2003 to zero and stays there. It matches the data almost exactly.

a. This column indicates the method of obtaining the Gamma distribution. EB/yr indicates that the Empirical Bayes method was used and the yearly data is the source of the variability. EB/PL indicates that the Empirical Bayes method was used and the plant to plant data is the source of the variability. NI means that the non-informative prior was used to obtain a distribution (this generally means that the data were sparse or that there is no variability in the data).

b. The p-value is 0.02, which is statistically significant but not highly statistically significant. LOOP performance during operational periods varies widely from year to year and the events are often not independent. At this point, it is not feasible to obtain a baseline period that is homogeneous.

c. No test p-value is reported because there is only one event in the industry exposure time from 1988 to 2010.
