EXECUTIVE SUMMARY

Some human-made radionuclides were detected in samples collected during the second quarter of 2023. None of the radionuclides detected in samples collected during the second quarter of 2023 could be directly linked with INL Site activities. All detected radionuclide concentrations were well below standards set by the U.S. Department of Energy (DOE) and regulatory standards established by the U.S. Environmental Protection Agency (EPA) for protection of the public.

This report for the second quarter of 2023 contains results from the INL Site environmental surveillance program's monitoring of the U.S. Department of Energy's Idaho National Laboratory (INL) Site's onsite, boundary and offsite location environment, April 1 through June 30, 2023. All sample types (media) and the sampling schedule followed during 2023 are listed in Appendix A. This report contains results for the following sample types:

- Air, including particulate air filters, charcoal cartridges, and atmospheric moisture
- Precipitation
- Drinking/surface water
- Milk
- OSLDs
- Large Game Animal Sampling.

Table ES-1. Summary of results for the second quarter of 2023.

Media	Sample Type	Analysis	Results
Air	Particulate Filters	Gross alpha, gross beta	There were no statistically significant differences among groups for the quarter or any month during the quarter for gross alpha concentrations, as well as gross beta concentrations for the months of April and May. Statistically significant differences were observed for gross beta concentrations for the quarter and the month of June. No result exceeded the Derived Concentration Standard (DCS) or 99%/95% upper tolerance limit (UTL) for gross alpha or gross beta activity in air.
	Quarterly Composite	Gamma-emitting radionuclides, strontium-90, actinides (americium, plutonium, and uranium)	Strontium-90 was detected in quarterly composite samples from Arco and INTEC (West Side). Plutonium-239/240 was detected in the duplicate composite sample from Idaho Nuclear Technology and Engineering Center (INTEC), however, no $^{239/240}$Pu was detected in the other composite sample collected from INTEC. Uranium radionuclides were detected in a few composite samples which suggest a natural origin. Human-made gamma-emitting radionuclides (e.g., cesium-137), americium-241, and plutonium-238 were not detected in any of the second quarter composite air samples.
	Charcoal Cartridge	Iodine-131	Iodine-131 was not detected in any of the batches of charcoal cartridges counted during the quarter.
Atmospheric Moisture	Liquid	Tritium	None of the sample results showed tritium concentrations greater than the 3s uncertainty during the quarter. No sample result exceeded the UTL or DCS for tritium in air.
Precipitation	Liquid	Tritium	A total of 23 samples were collected during the second quarter. None of the tritium results were greater than the 3s uncertainty.
Drinking/Surface Water	Liquid	Gross alpha, gross beta, tritium	Gross alpha was detected in two of ten drinking water samples and none of the three surface water samples. Gross beta was detected in eight of ten drinking water samples and in all three surface water samples. All concentrations were generally similar to previous results.

Table ES-1. continued.

Media	Sample Type	Analysis	Results
			Tritium was detected in two drinking water samples and two surface water samples. Concentrations were similar to those measured historically in drinking and surface water and well below the DCS for tritium in drinking water.
Milk	Liquid	Iodine-131, other gamma-emitting radionuclides, strontium-90, tritium	Forty-two milk samples were collected at seven locations (including the offsite control sample from Colorado and two duplicates). No ^{131}I was detected, however, a milk sample collected in April resulted in a ^{137}Cs value which was slightly greater than 3s. Additional review of the result and uncertainty suggest the data could be a false positive. Strontium-90 was not detected in any of the milk samples analyzed. The results are within the range of the past several years. Tritium was detected in one of the samples analyzed. The result was well below the DCS for tritium in milk.
Environmental Dosimeters	External radiation	Gamma-emittingand neutron radioactivity	Measurements of environmental radiation made using optically stimulated luminescent dosimeters (OSLDs) were primarily below the background level UTL except for select locations at INTEC (listed as Idaho Chemical Processing Plant or ICPP), and the Advanced Test Reactor Complex (listed as Test Reactor Area or TRA). Measurements that exceeded the UTL are within historical values and/or likely due to operations in those areas. Neutron dose monitoring performed at INL buildings and facilities were reported to be below the minimum measurable quantity of 10 mrem.
Large game animals	Tissue	Gamma-emitting radionuclides	No human-made gamma-emitting radionuclides were found in any of the tissue samples collected in second quarter.

1. INL Contractor Program Description

Operations at the Idaho National Laboratory (INL) Site are conducted under requirements imposed by the U.S. Department of Energy (DOE) under authority of the Atomic Energy Act and the U.S. Environmental Protection Agency (EPA) under several acts (e.g., the Clean Air Act and Safe Drinking Water Act). The requirements imposed by DOE are specified in DOE Orders. These requirements include those to monitor the effects of DOE activities both inside and outside the boundaries of DOE facilities (DOE 2011, DOE 2015).

During calendar year 2023, environmental surveillance within the INL Site boundaries was primarily the responsibility of the INL and Idaho Cleanup Project (ICP) contractors. The INL contractor also provides surveillance off the INL Site.

This report contains surveillance monitoring results from the INL contractor for samples collected during the second quarter of 2023 (April 1 – June 30, 2023).

The INL environmental surveillance program is designed to satisfy the following objectives:

- verify compliance with applicable environmental laws, regulations, and DOE Orders
- characterize and define trends in the physical, chemical, and biological condition of environmental media on and around the INL Site
- assess the potential radiation dose to members of the public from INL Site effluents
- present laboratory data which has been reviewed using an EPA quality assurance process.

The goal of the surveillance program is to monitor different media at a number of potential exposure points within the various exposure pathways, including air, water, agricultural products, wildlife, and soil that could possibly contribute to the radiation dose received by the public.

Environmental samples collected include:

- air at 37 low-volume air samplers (four of which are used as replicate samplers) at 33 locations on and around the INL Site
- atmospheric moisture at two INL Site locations and at four locations off the INL Site
- precipitation collected at one INL Site location and three locations off the INL Site
- drinking water collected from eight locations off the INL Site
- surface water collected from three springs located downgradient of the INL Site and from five locations along the Big Lost River, when it is flowing, on the INL Site
- agricultural products, including milk at six dairies around the INL Site, potatoes from at least eight regional producers, alfalfa from three locations off the INL Site, grain (wheat and barley) from approximately nine regional producers, and lettuce from approximately seven home-owned and portable gardens on and around the INL Site
- soil from 30 locations on and around the INL Site once every five years
- environmental dosimeters from 196 (includes duplicates) locations semi-annually
- various numbers of wildlife including bats, big game (pronghorn, mule deer, and elk) and waterfowl sampled from the INL Site.

Table A-1 in Appendix A lists samples, sampling locations, and collection frequency for the INL contractor.

Three laboratories were used to perform analyses on routine environmental samples collected during the quarter identified in this report. The INL Environmental Services In Situ Gamma Laboratory was used to scan charcoal cartridges for gamma-emitting radionuclides. The Idaho State University Environmental Assessment Laboratory performed routine gross alpha, gross beta, tritium, and gamma spectrometry analyses. GEL Laboratories performed routine gross alpha, gross beta, and gamma spectrometry analyses. Analyses requiring radiochemistry including strontium-90 (^{90}Sr), plutonium-238 (^{238}Pu), plutonium-239/240 ($^{239/240}$Pu), uranium-233/234 ($^{233/234U}$), uranium-235 (^{235}U), uranium-238 (^{238}U) and ^{241}Am were also performed by GEL Laboratories.

In the event of non-routine occurrences, such as suspected releases of radioactive material, the INL contractor may increase the frequency of sampling and/or the number of sampling locations based on the nature of the release and wind distribution patterns. Any data found to be outside historical norms is thoroughly investigated to determine if an INL Site origin is likely. Investigation may include re-sampling and/or re-analysis of prior samples.

In the event of any suspected worldwide nuclear incidents, like the 1986 Chernobyl accident or the 2011 Fukushima accident, the EPA may request additional sampling be performed through RadNet. RadNet is a nationwide environmental radiation monitoring system that monitors the nation's air, precipitation, and drinking water for radiation. The INL contractor currently operates a high-volume air sampler and collects precipitation and drinking water in Idaho Falls for this national program and routinely sends samples to EPA's Eastern Environmental Radiation Facility for analyses. The RadNet data collected at Idaho Falls are not reported by the INL contractor but are available through the EPA RadNet website (https://www.epa.gov/radnet).

Once samples have been collected and analyzed, the INL contractor has the responsibility for quality control of the data, entry into databases, and reporting in quarterly reports. The quarterly reports are then consolidated into the INL Site Environmental Report for each calendar year. The annual report also includes data collected by other INL Site contractors.

The results reported in the quarterly and annual reports are assessed in terms of data quality and statistical significance with respect to laboratory analytical uncertainties, sample locations, reported INL Site releases, meteorological data, and worldwide events that might conceivably affect the INL Site environment. First, field collection and laboratory information are reviewed to determine identifiable errors that would invalidate or limit use of the data. Examples of such limitations include insufficient sample volume, torn filters, evidence of laboratory cross-contamination or quality control issues. Data that pass initial screening are further evaluated using statistical methods. Statistical tools are necessary for data evaluation particularly since environmental measurements typically involve the determination of minute concentrations, which are difficult to detect and even more difficult to distinguish from other measurements.

Results are presented in this report with an analytical uncertainty term, s, where 's' is the estimated sample standard deviation (σ), assuming a Gaussian or normal distribution. All results are reported in this document, even those that do not necessarily represent detections. The term' detected,' as used for the discussion of results in this report, does not imply any degree of risk to the public or environment, but rather indicates that the radionuclide was measured at a concentration sufficient for the analytical instrument to record a value that is statistically different from background. Laboratory measurements involve the analysis of a target sample and the analysis of a prepared laboratory blank (i.e., a sample which is identical to the sample collected in the environment, except that the radionuclide of interest is

absent). In order to conclude that a radionuclide has been detected, it is essential to consider two fundamental aspects of the problem of detection: (1) the instrument signal for the sample must be greater than that observed for the blank before the decision can be made that the radionuclide has been detected; and (2) an estimate must be made of the minimum radionuclide concentration that will yield a sufficiently large observed signal before the correct decision can be made for detection or non-detection. Each laboratory currently defines a detection of radioactivity in an individual sample if the result exceeds a detection level calculated by the laboratory after the analysis of a background sample, based on calculations derived by Currie (1984). The minimum detectable concentration (MDC) is defined as the concentration at which there is a 95% confidence that an analyte signal will be distinguishable from an analyte-free sample.

In addition, the INL contractor uses a three standard deviation criterion to minimize the chance that a potentially false positive result is included in the data set. Statistically, the probability that a result can exceed the absolute value of its total uncertainty at three standard deviations by chance alone is less than 1%. A result that is greater than three times the total uncertainty of the measurement represents a statistically positive detection with over 99% confidence (DOE 2022a). The INL contractor reports measured radionuclide concentrations greater than or equal to their respective 3s uncertainties as being detected with confidence.

Concentrations between 2s and 3s are reported as questionably detected. That is, the radionuclide may be present in the sample; however, the probability that a result can exceed the absolute value of its total uncertainty at two standard deviations by chance alone may be as high as 5%. Measurements made between 2s and 3s are examined further to determine if they are a part of a pattern (temporal or spatial) that might warrant further investigation or recounting. For example, if a radionuclide is routinely detected at > 3s at a specific location, a sample result between 2s and 3s might be considered detected.

If a result is less than or equal to 2s there is even less statistical confidence that the radionuclide is present in the sample. Analytical results in this report are presented as the result value ± one standard deviation (1s) for reporting consistency with the annual report. To obtain the 2s or 3s values simply multiply the uncertainty term by 2 or 3.

Data are also compared to historical measurements using the upper tolerance limit (UTL). The UTL is a value such that 99% of the population (all valid measurements made between 2011-2020) is less than the UTL with 95% confidence (EPA 2015). With a 99%/95% UTL it is expected that approximately 1% of the measurements will exceed the UTL if the concentration of a radionuclide is within the normal range. This means that if a concentration exceeds the UTL it does not necessarily indicate that the sampling location is outside of the normal range. Rather, it indicates that the measurement should be closely examined to determine if it is unusually high.

For more information concerning the INL environmental surveillance program, please email George.KrauszerII@inl.gov, or visit https://inl.gov/environmental-monitoring/.

2. INL Site

The INL Site is a nuclear energy and homeland security research and environmental management facility. It is owned and administered by the DOE, Idaho Operations Office and occupies about 890 mi^2 (2,300 km^2) of the upper Snake River Plain in Southeastern Idaho (Figure 1). The history of the INL Site began during World War II when the U.S. Naval Ordnance Station was located in Pocatello, Idaho. This station, one of two such installations in the U.S., retooled large guns from U.S. Navy warships. The retooled guns were tested on the nearby, uninhabited plain, known as the Naval Proving Ground. In the years following the war, as the nation worked to develop nuclear power, the Atomic Energy Commission, predecessor to the DOE, became interested in the Naval Proving Ground and made plans for a facility to build, test, and perfect nuclear power reactors.

The Naval Proving Ground became the National Reactor Testing Station (NRTS) in 1949, under the Atomic Energy Commission. By the end of 1951, a reactor at the NRTS became the first to produce useful amounts of electricity. Over time the site has operated 52 various types of reactors, associated research centers, and waste handling areas. The NRTS was renamed the Idaho National Engineering Laboratory in 1974, and the Idaho National Engineering and Environmental Laboratory (INEEL) in January 1997. With renewed interest in nuclear power the DOE announced in 2003 that Argonne National Laboratory and the INEEL would be the lead laboratories for development of the next generation of power reactors. On February 1, 2005, the INEEL and Argonne National Laboratory-West became the INL. The INL is committed to providing international nuclear leadership for the 21st Century, developing and demonstrating compelling national security technologies, and delivering excellence in science and technology as one of the DOE's multi-program national laboratories. Battelle Energy Alliance, LLC, is responsible for the management and operations of the INL.

The ICP is a separately managed effort. The ICP is charged with safely and cost-effectively completing the majority of cleanup work from past laboratory missions in an ongoing process. The Idaho Environmental Coalition, LLC, is responsible for the ICP.

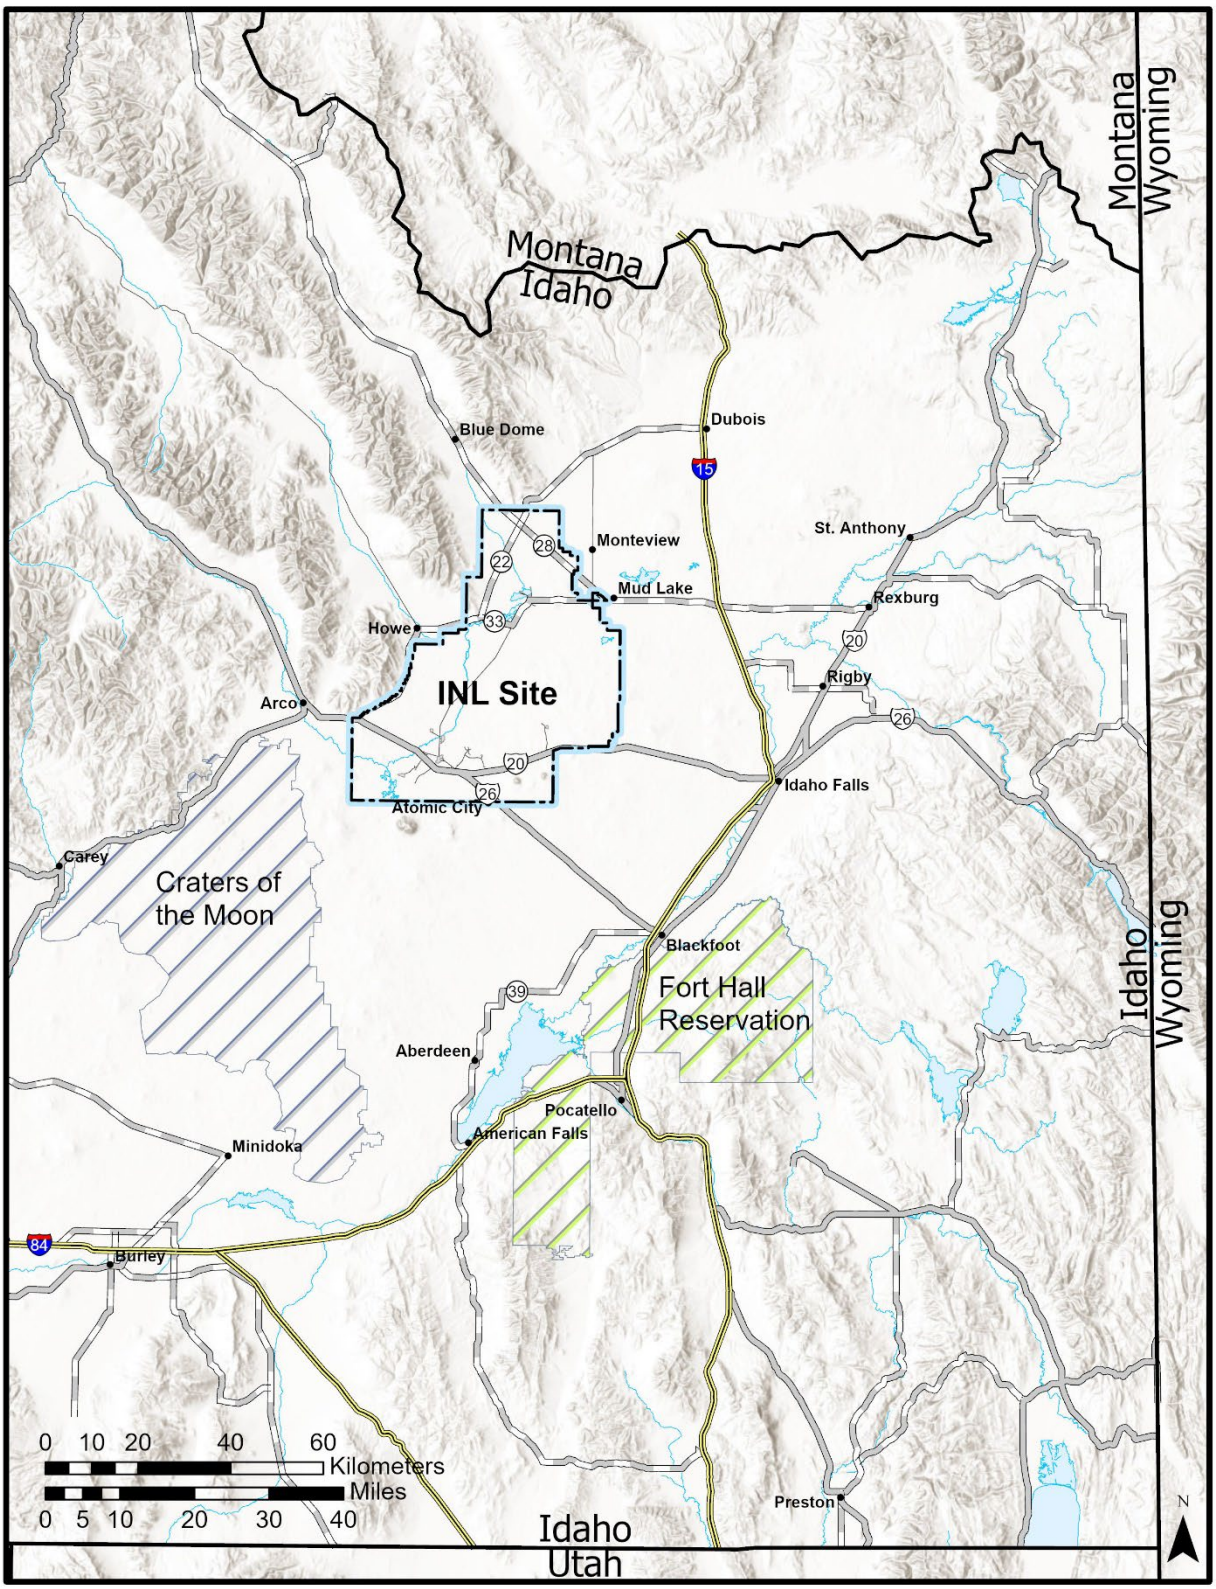

Figure 1. Location of the INL Site.

3. Air Sampling

The primary pathway by which radionuclides can move off the INL Site is through the air and for this reason the air pathway is the primary focus of monitoring on and around the INL Site. Samples for particulates and iodine-131 (^{131}I) gas in air were collected weekly for the duration of the quarter at 33 locations using low-volume air samplers. Moisture in the atmosphere was sampled at six locations around the INL Site and analyzed for tritium. Air sampling activities and results for the second quarter of 2023 are discussed below. A summary of approximate MDCs for radiological analyses and DOE Derived Concentration Standard (DCS) (DOE 2022b) values is provided in Appendix B.

3.1 Low-volume Air Sampling

Radioactivity associated with airborne particulates was monitored continuously by 37 low-volume air samplers (four of which are used as replicate samplers) at 33 locations during the second quarter of 2023 (Figure 2). Twenty-one of these samplers are located onsite, seven are situated off the INL Site near the boundary, and nine have been placed at locations off the INL Site. Samplers are divided into onsite, boundary, and offsite groups to determine if there is a gradient of radionuclide concentrations, increasing towards the INL Site. Each replicate sampler is relocated every other year to a new location. During the second quarter 2023, replicate samplers were located at Dubois (offsite location), Idaho Nuclear Technology and Engineering Center (INTEC) – westside (onsite location), Radioactive Waste Management Complex (RWMC) (onsite location), and Van Buren (onsite location). Particulates in air were collected on membrane particulate filters (1.2 μm pore size). Gases passing through the filter were collected with an activated charcoal cartridge.

Filters and charcoal cartridges were changed weekly at each station during the quarter. Each particulate filter was analyzed for gross alpha and gross beta radioactivity using thin-window gas flow proportional counting systems after waiting about four days for shorter-lived naturally-occurring daughter products of radon and thorium to decay.

The weekly particulate filters collected during the quarter for each location were composited and analyzed for gamma-emitting radionuclides. Composites were also analyzed by location for ^{90}Sr, ^{238}Pu, $^{239/240}$Pu, $^{233/234}$U, ^{238}U and ^{241}Am.

Charcoal cartridges were analyzed for gamma-emitting radionuclides, specifically for ^{131}I, using two methods. Cartridges analyzed by Idaho State University Environmental Assessment Laboratory are done in batches of eleven as an initial scan. If the scan results in ^{131}I activity above 3-sigma, the cartridges are split into smaller batches and analyzed to identify the cartridge which contains the radioanalyte above 3-sigma. Cartridges which are analyzed by the INL Environmental Services In Situ Gamma Laboratory are scanned individually. If the scan of an individual cartridge results in a positive detection, the cartridge is shipped to GEL Laboratories for analysis. Iodine-131 is of particular interest because it is produced in relatively large quantities by nuclear fission, is readily accumulated in human and animal thyroids, and has a half-life of eight days. This means that any elevated level of ^{131}I in the environment could be from a recent release of fission products.

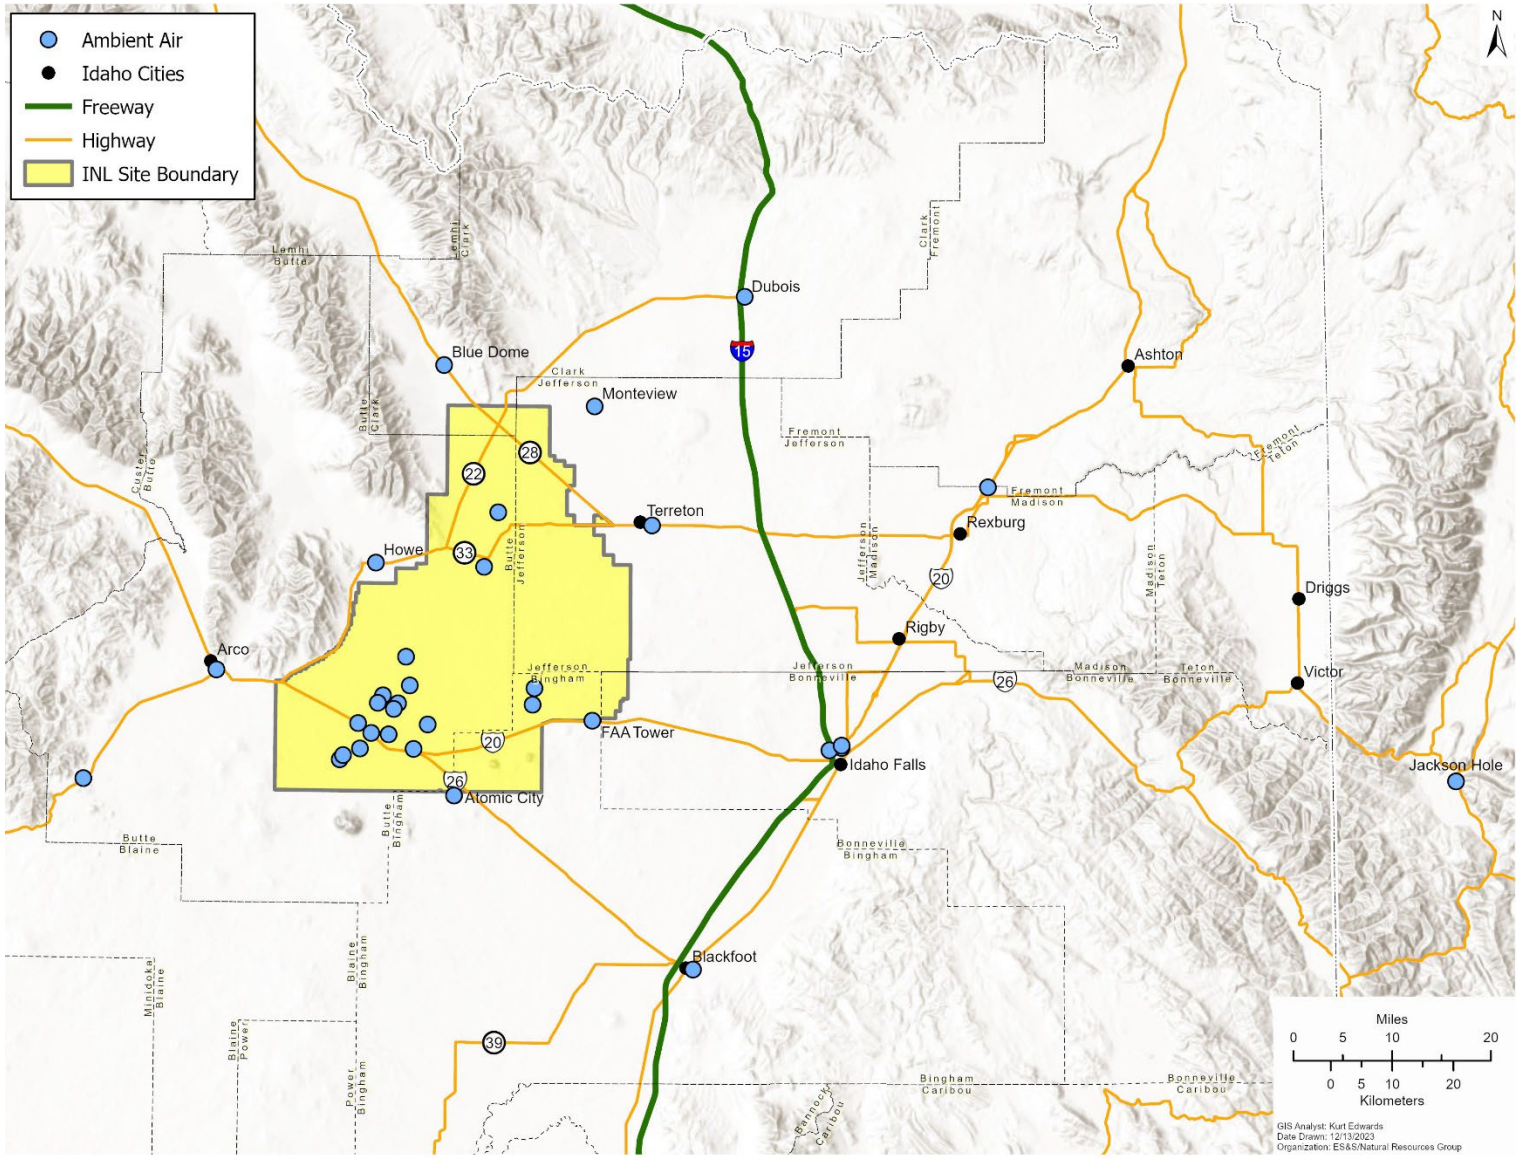

Figure 2. INL contractor air monitoring locations.

Gross alpha results are reported in Table C-1 and shown in Figures 3 through 6. Gross alpha concentrations measured in individual samples ranged from a low of $(-1.2 \pm 6.6) \times 10^{-16}$ µCi/ml collected at Atomic City on June 6, 2023, to a high of $(4.6 \pm 0.5) \times 10^{-15}$ µCi/ml collected at Dubois on May 23, 2023. All results were less than the DCS of 1.1×10^{-13} µCi/ml for $^{239/240}$Pu (see Table B-1 of Appendix B). In addition, the results were consistent with historical data, as represented by the 99%/95% UTL for gross alpha activity (4.8×10^{-15} µCi/ml). The UTL was determined using ten years of historical data (measured from 2011 through 2020) and the ProUCL statistical software (https://www.epa.gov/land-research/proucl-software). The 99%/95% UTL is a value such that 99% of the population (all possible air measurements) is less than the UTL with 95% confidence. With a 99%/95% UTL it is expected that approximately 1% of the measurements will exceed the UTL if the concentration of gross alpha is within the normal range. This means if a concentration exceeds the UTL it does not necessarily indicate that the result is outside of the normal range. Rather, it indicates that the measurement should be closely examined to determine if it is unusually high.

Gross alpha data have been tested for distribution (normally or lognormally distributed) and generally show no consistent discernible distribution. Because there is no discernible distribution of the data, a parametric test of significance cannot be used. The nonparametric Kruskal-Wallis analysis of variance by ranks test of multiple independent groups was used to determine statistical differences between onsite, boundary, and offsite locations. The test assesses the hypothesis that the different samples in the comparison were drawn from the same distribution or from distributions with the same median. In the computation of the Kruskal-Wallis test, each of the N observations is replaced by a rank. That is, all the results from all the locations are combined and ranked in a single series with the smallest result replaced by rank 1 and the largest result replaced by rank N (i.e., the total number of results). The sum of the ranks in each location group (i.e., onsite, boundary, and offsite) is found and then averaged for each group. If the samples are from the same populations, the average ranks should be about the same, whereas if the samples are from populations with different medians, the average ranks should differ. Statistically significant difference exists between data groups if the p-value (or probability value) is less than 0.05. Values greater than 0.05 translate into a 95% confidence that the medians are statistically the same. The p-value for each comparison is shown in Table D-1. There was no statistically significant differences among groups for the quarter, or any month during the quarter (Table D-1). To determine if there were any differences between stations and where the differences occur, the Kruskal-Wallis analysis of variance by ranks test was used again. No differences were determined between stations (Table D-2).

Gross beta results are presented in Table C-1 and displayed in Figures 7 through 10. Gross beta concentrations measured in individual samples ranged from a low of $(4.8 \pm 3.5) \times 10^{-16}$ µCi/ml collected at Van Buren (QA) on June 13, 2023, to a high of $(49.9 \pm 1.0) \times 10^{-15}$ µCi/ml collected at Howe on May 30, 2023. The typical temporal fluctuations in gross beta concentrations in air were observed during the quarter because of temperature inversions. All results were less than the DCS of 9.6×10^{-12} µCi/ml for ^{90}Sr (see Table B-1 of Appendix B). In addition, the results were consistent with historical data, as represented by the 99%/95% UTL for gross beta activity (6.1×10^{-14} µCi/ml). The data were tested quarterly and generally are found to be neither normally nor log-normally distributed. Box and whiskers plots were used to present the non-parametric data. Outliers and extreme values were retained in subsequent statistical analyses because they are within the range of measurements made in the past ten years, and because these values could not be attributed to mistakes in collection, analysis, or reporting procedures.

There were no statistically significant differences in the gross beta data between groups for April and May (Table D-1), however, statistically significant differences did occur for the quarter and the month of June. To determine if there were any differences between stations and where the differences occur, multiple comparisons were also made using the Kruskal-Wallis analysis of variance by ranks test between gross

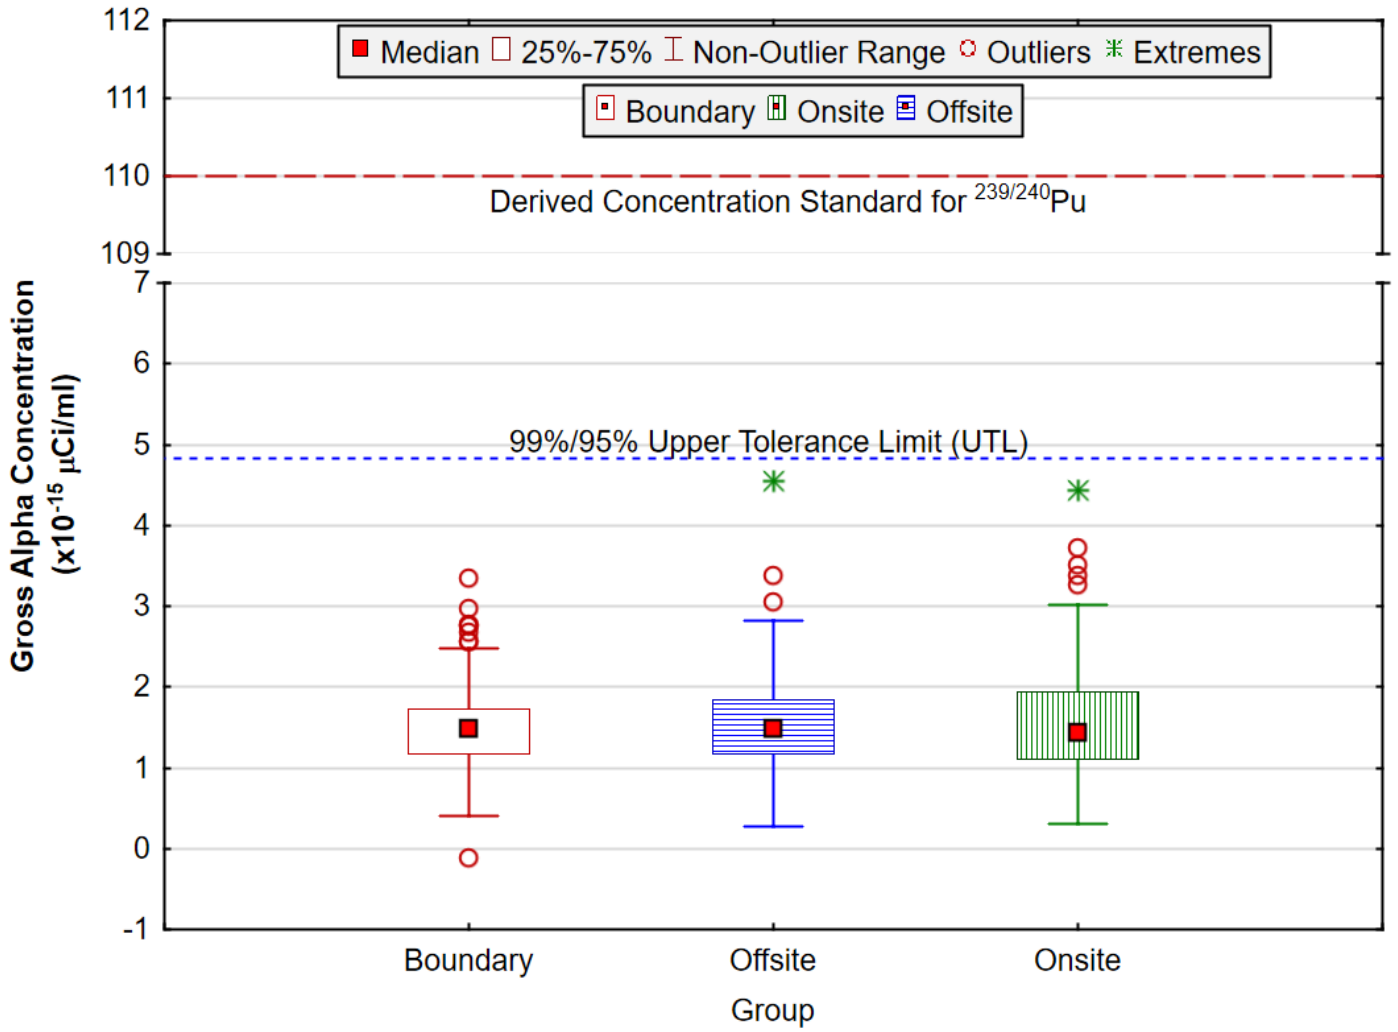

Figure 3. Gross alpha concentrations in air at onsite, boundary, and offsite locations for the second quarter of 2023. The DCS is the concentration of $^{239/240}$Pu in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{238}U, ^{234}U, ^{232}Th, ^{226}Ra, and ^{210}Po) in uncertain proportions, a meaningful DCS cannot be constructed for gross alpha concentrations. The DCS for $^{239/240}$Pu is shown because it is the most restrictive human-made alpha emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

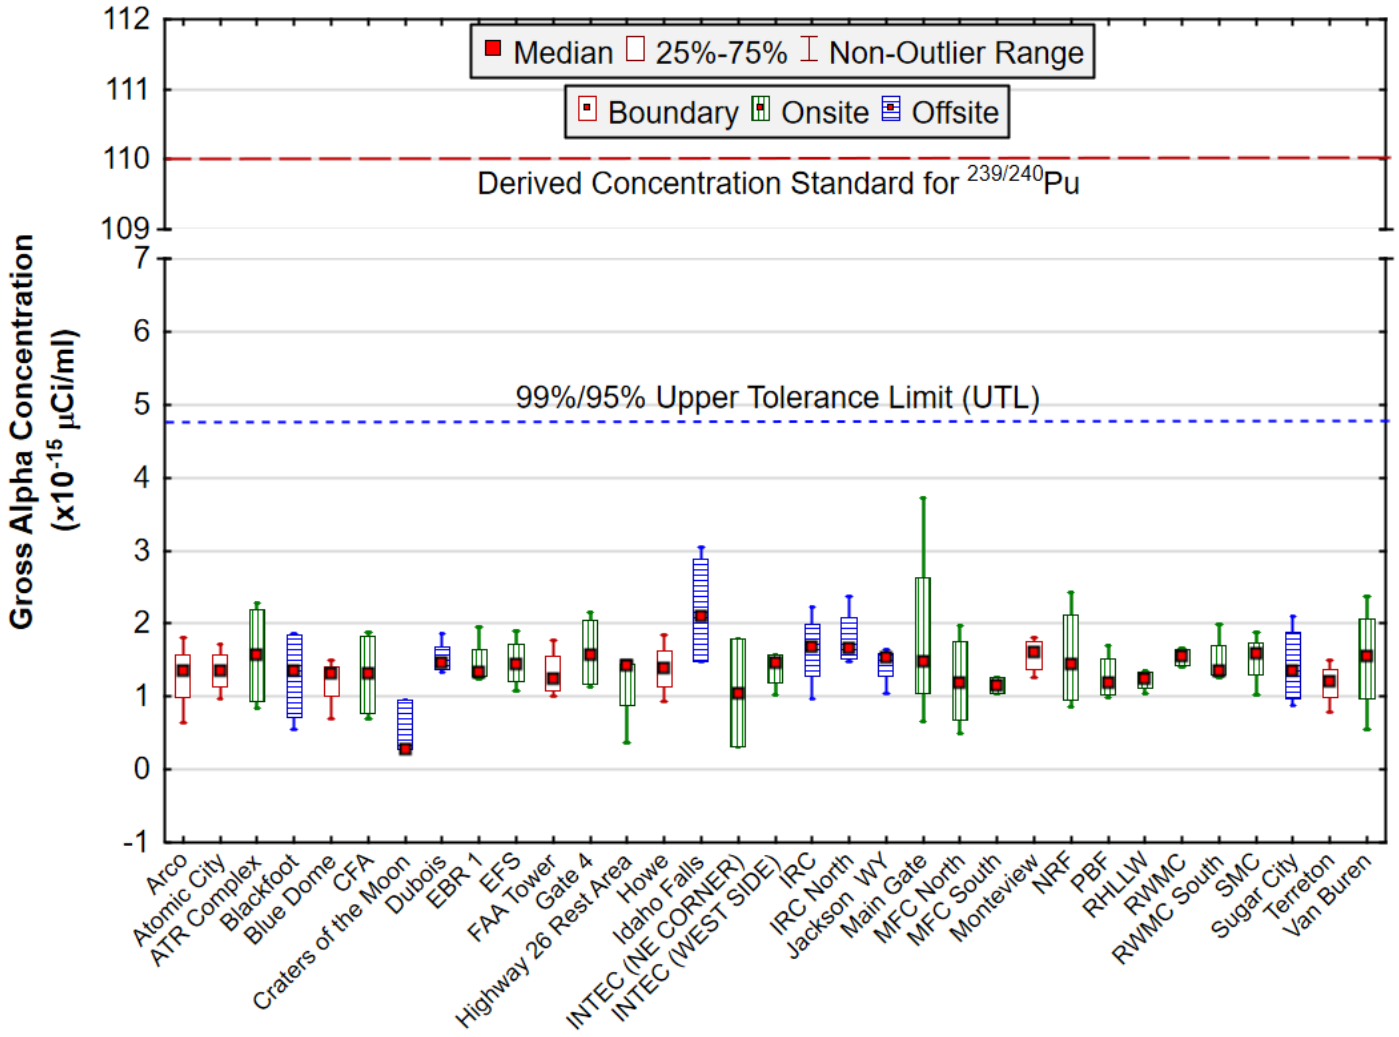

Figure 4. April 2023 gross alpha concentrations in air at onsite, boundary, and offsite locations. The DCS is the concentration of $^{239/240}Pu$ in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{238}U, ^{234}U, ^{232}Th, ^{226}Ra, and ^{210}Po) in uncertain proportions, a meaningful DCS cannot be constructed for gross alpha concentrations. The DCS for $^{239/240}Pu$ is shown because it is the most restrictive human-made alpha emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

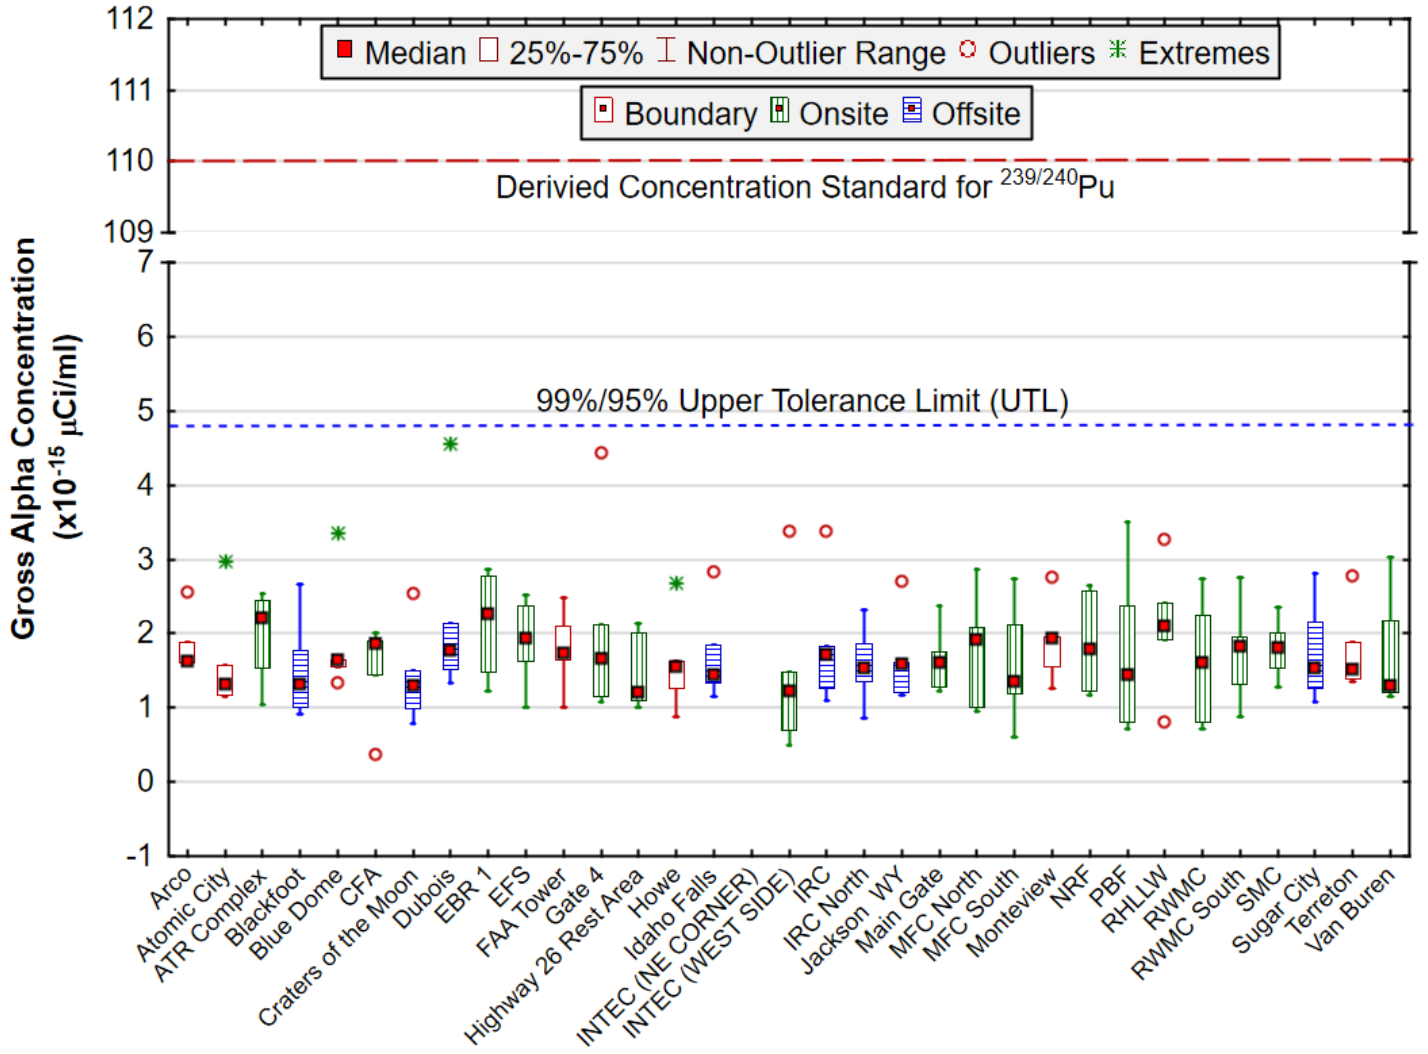

Figure 5. May 2023 gross alpha concentrations in air at onsite, boundary, and offsite locations. The DCS is the concentration of $^{239/240}Pu$ in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{238}U, ^{234}U, ^{232}Th, ^{226}Ra, and ^{210}Po) in uncertain proportions, a meaningful DCS cannot be constructed for gross alpha concentrations. The DCS for $^{239/240}Pu$ is shown because it is the most restrictive human-made alpha emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

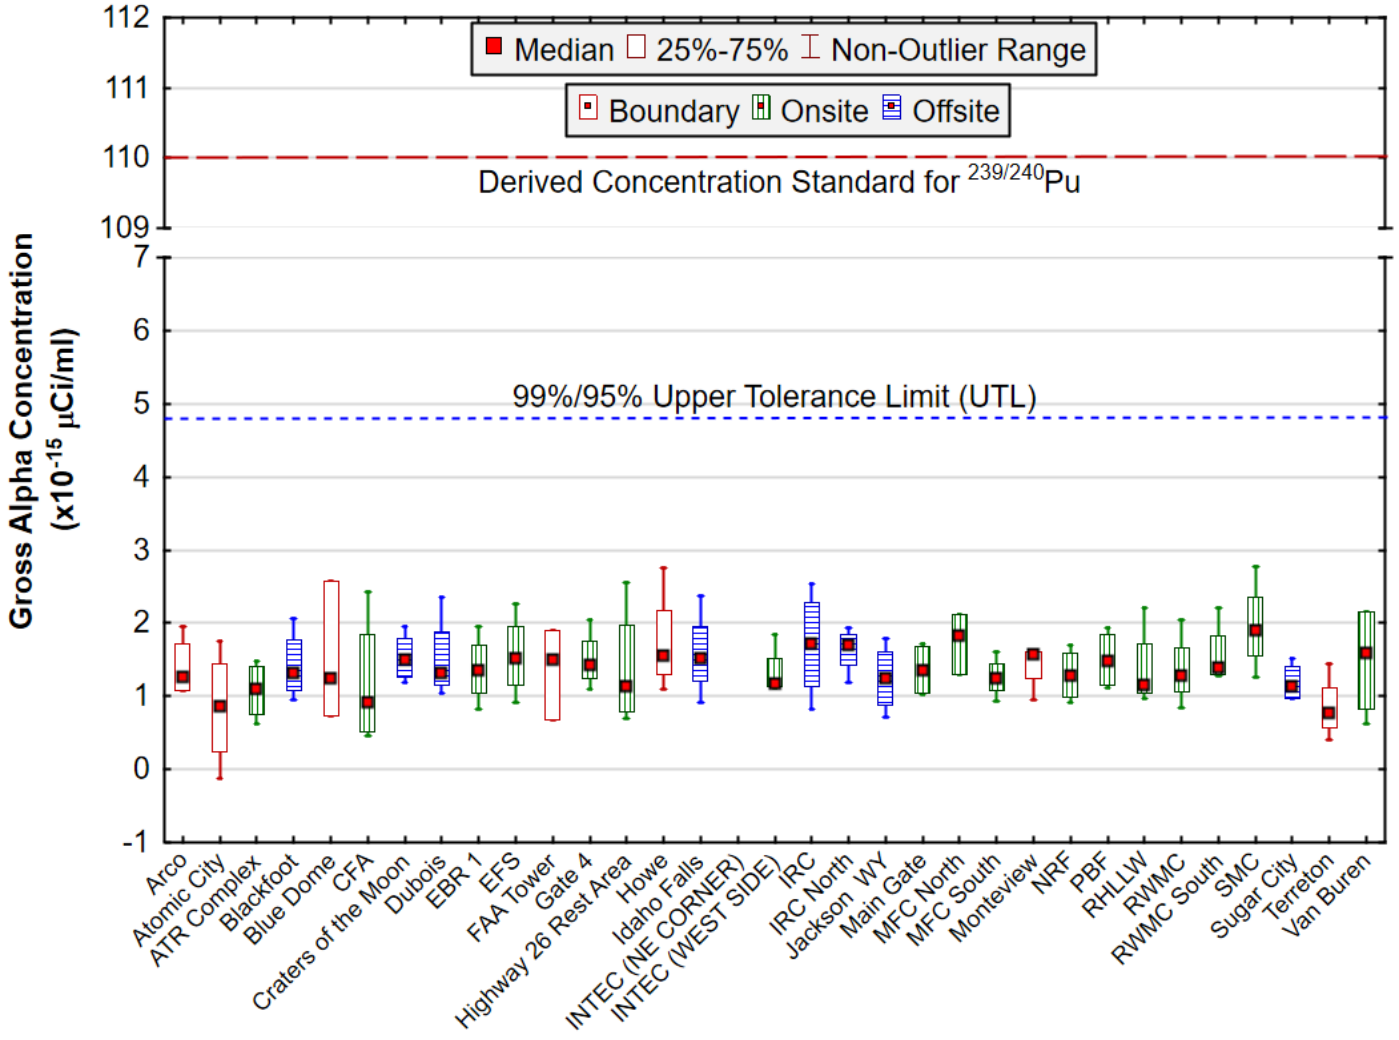

Figure 6. June 2023 gross alpha concentrations in air at onsite, boundary, and offsite locations. The DCS is the concentration of $^{239/240}Pu$ in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{238}U, ^{234}U, ^{232}Th, ^{226}Ra, and ^{210}Po) in uncertain proportions, a meaningful DCS cannot be constructed for gross alpha concentrations. The DCS for $^{239/240}Pu$ is shown because it is the most restrictive human-made alpha emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

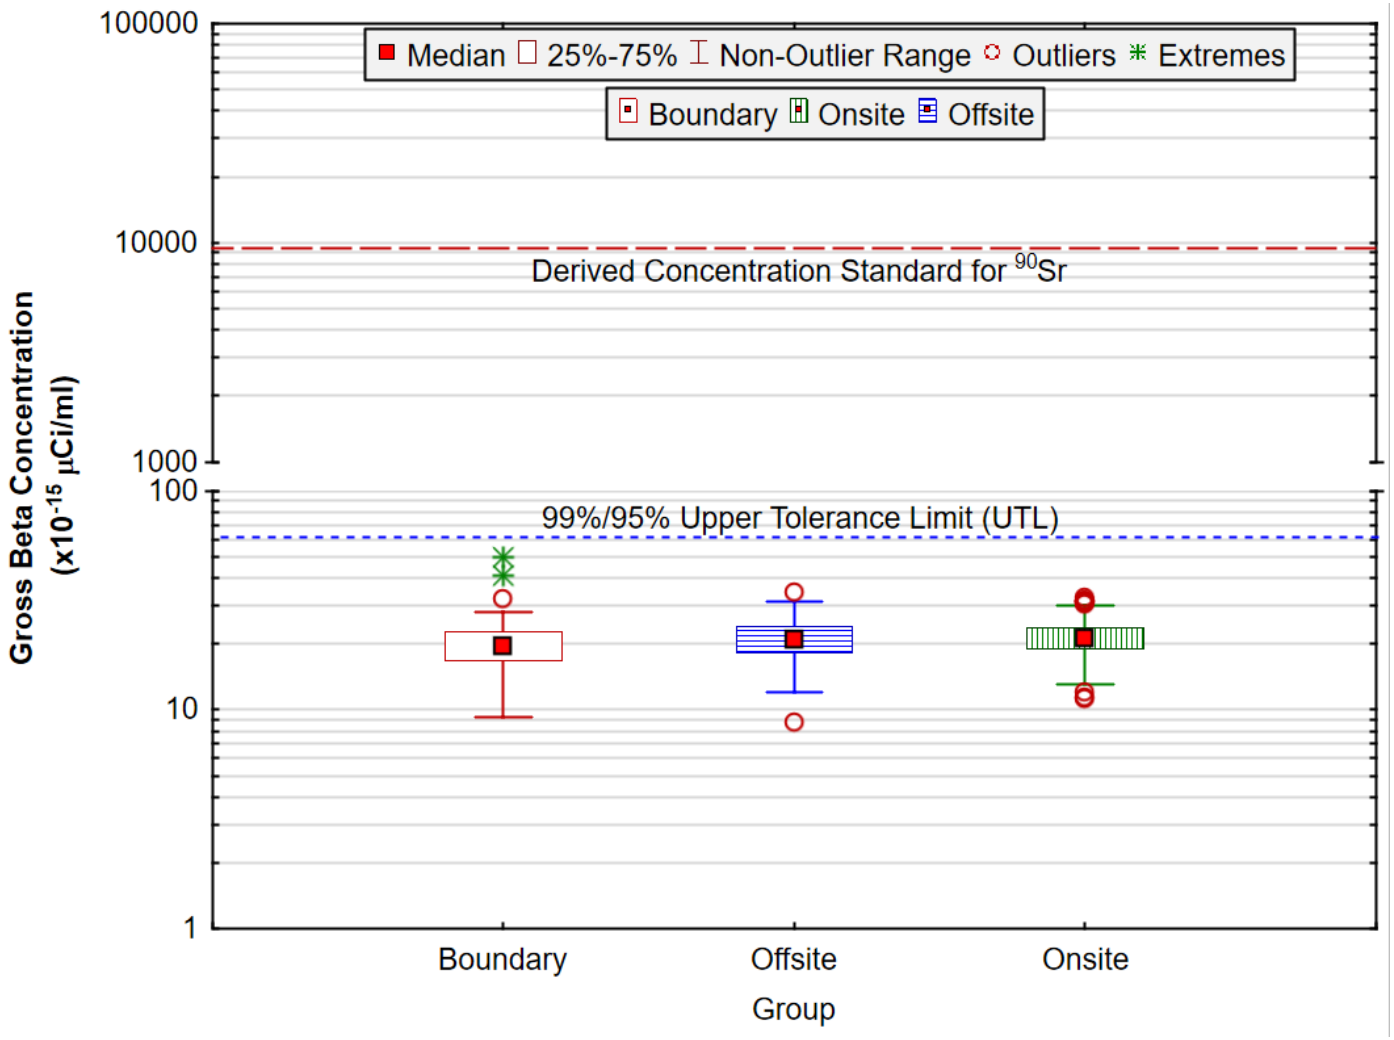

Figure 7. Gross beta concentrations in air at onsite, boundary, and offsite locations for the second quarter of 2023. The DCS is the concentration of ^{90}Sr in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{40}K, ^{228}Ra, and ^{210}Pb) in uncertain proportions, a meaningful DCS cannot be constructed for gross beta concentration. The DCS for ^{90}Sr is shown because it is the most restrictive human-made beta emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

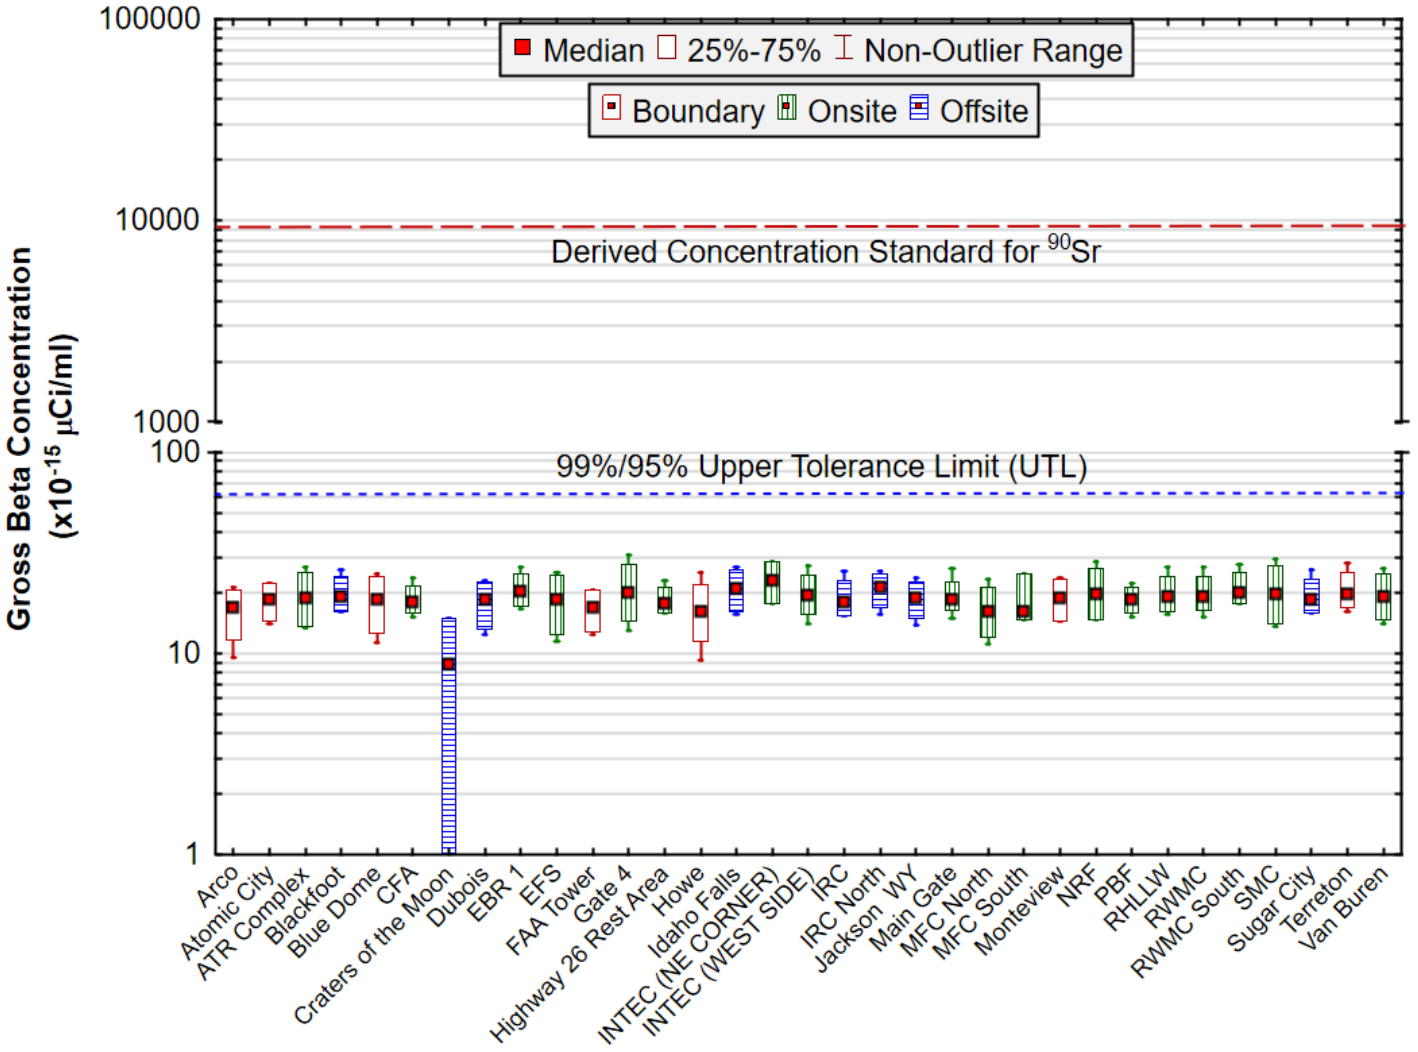

Figure 8. April 2023 gross beta concentrations in air at onsite, boundary, and offsite locations. The DCS is the concentration of ^{90}Sr in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{40}K, ^{228}Ra, and ^{210}Pb) in uncertain proportions, a meaningful DCS cannot be constructed for gross beta concentrations. The DCS for ^{90}Sr is shown because it is the most restrictive human-made beta emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

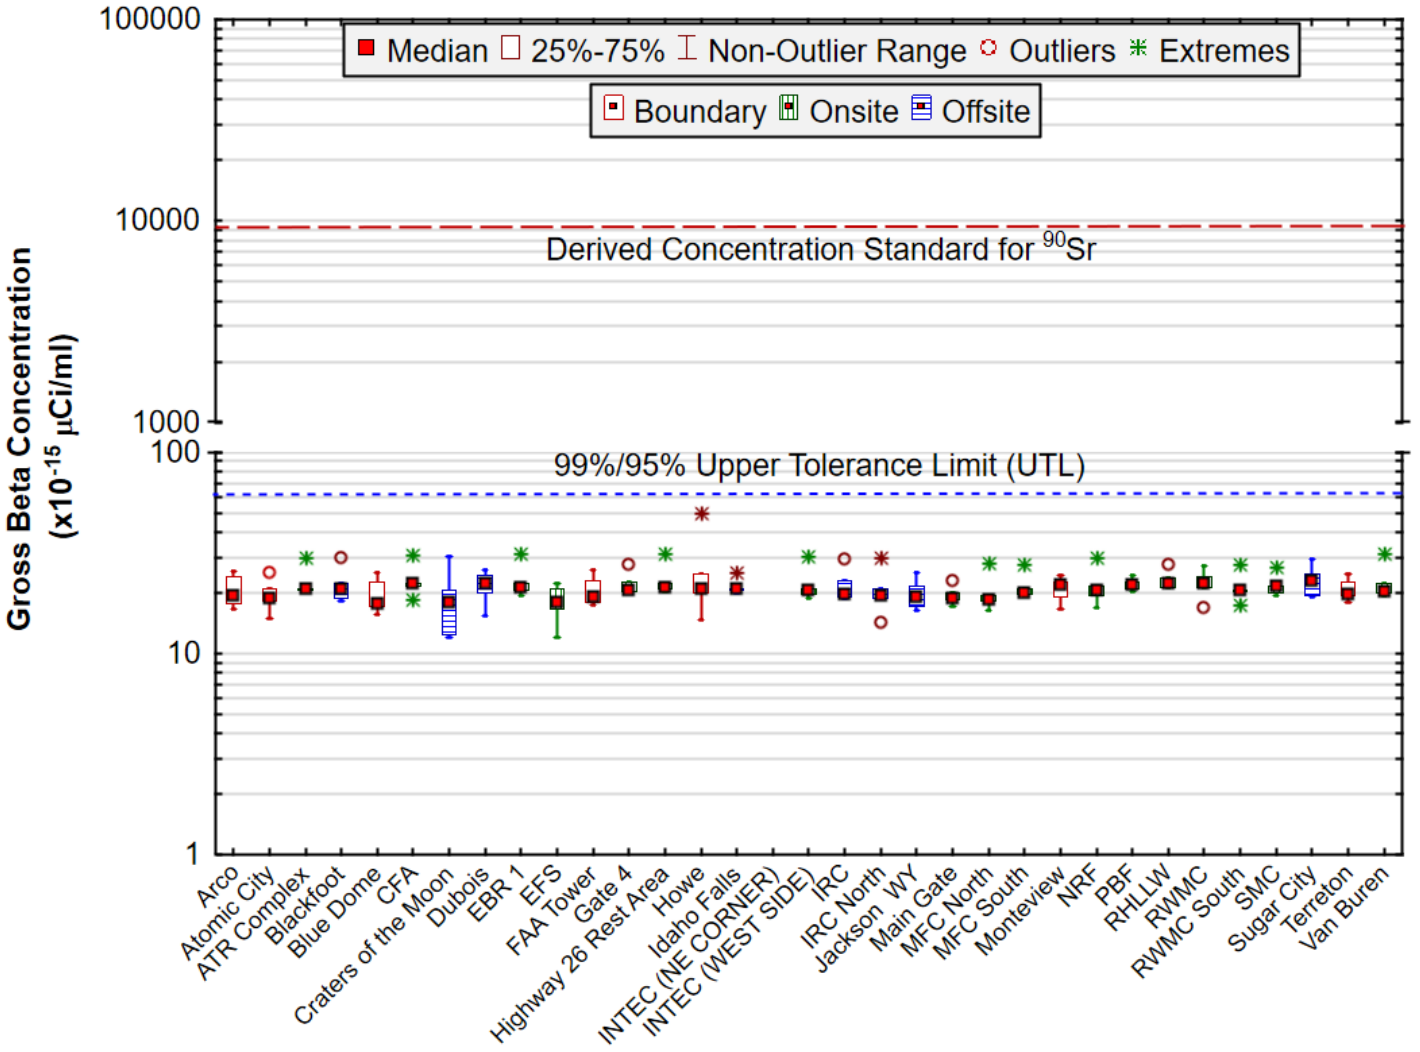

Figure 9. May 2023 gross beta concentrations in air at onsite, boundary, and offsite locations. The DCS is the concentration of ^{90}Sr in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{40}K, ^{228}Ra, and ^{210}Pb) in uncertain proportions, a meaningful DCS cannot be constructed for gross beta concentrations. The DCS for ^{90}Sr is shown because it is the most restrictive human-made beta emitter. The UTL represents the value below which 99% of the population values are expected to fall with 95% confidence.

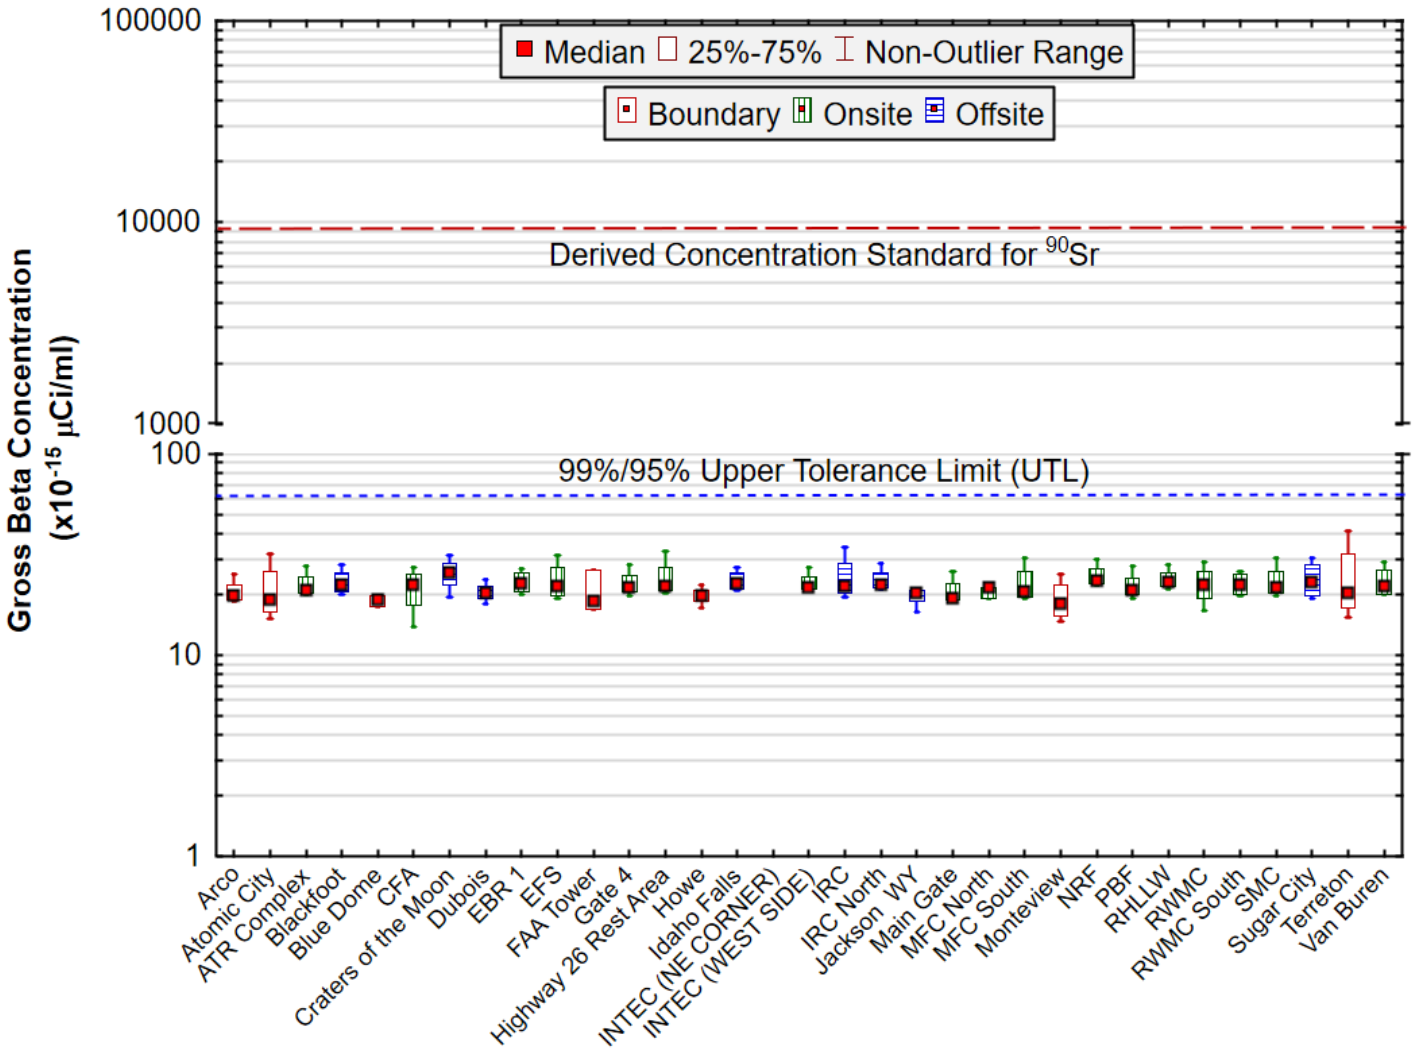

Figure 10. June 2023 gross beta concentrations in air at onsite, boundary, and offsite locations. The DCS is the concentration of ^{90}Sr in air which, if inhaled for a year, would result in a dose of 100 mrem/yr. Because the measurements include naturally occurring radionuclides (such as ^{40}K, ^{228}Ra, and ^{210}Pb) in uncertain proportions, a meaningful DCS cannot be constructed for gross beta concentrations. The DCS for ^{90}Sr is shown because it is the most restrictive human-made beta emitter. The UTL represents the value below which 99% of the population are expected to fall with 95% confidence.

beta concentrations measured at all locations. No differences were determined to have occurred between stations (Table D-3).

Iodine-131 was not detected in any of the charcoal cartridges measured during the second quarter. Weekly ^{131}I results for each location are listed in Table C-2.

Strontium-90, a beta-emitting radionuclide associated with historic nuclear weapons testing fallout, was detected in composite samples at Arco and INTEC (West Side) (Table C-3). Plutonium-239/240 was detected in a duplicate composite sample from INTEC. No $^{239/240}Pu$ was detected in the other composite sample collected from INTEC. Composite samples from Howe, Monteview, Dubois (QA), and Jackson, WY resulted in detections of uranium radionuclides. A UTL is not available as more data needs to be collected. Uranium occurs naturally in various rocks and soil, can be suspended in the air and captured on an air filter. The United Nations Scientific committee on the Effects of Atomic Radiation lists ^{238}U air concentrations in the United State to be between 2.43×10^{-17} µCi/mL to 1.35×10^{-16} µCi/mL (UNSCEAR 2000). All results were below the DCS values for these radionuclides in air (i.e. 9.6×10^{-12} µCi/mL for ^{90}Sr, 1.1×10^{-13} µCi/mL for $^{239/240}Pu$, 1.6×10^{-13} µCi/mL for $^{233/234}U$ and 1.8×10^{-13} µCi/mL for ^{238}U).

No ^{137}Cs or other human-made gamma-emitting radionuclides were found in quarterly air composites. Americium-241 and ^{238}Pu, alpha-emitting radionuclides, were not detected in any composite sample.

3.2 Atmospheric Moisture Sampling

Atmospheric moisture is collected by pulling air through a column of absorbent material (molecular sieve material) to absorb water vapor. The water is then extracted from the absorbent material by heat distillation. The resulting water samples are then analyzed for tritium using liquid scintillation.

Results were available for twenty-two atmospheric moisture samples collected at the onsite, boundary, and offsite locations during the second quarter of 2023 (Figure 11). None of the results exceeded the 3s uncertainty level for tritium. The maximum reported value of $(1.2 \pm 1.1) \times 10^{-12}$ µCi/mL$_{air}$ was at the Experimental Field Station (EFS). The maximum result is below the 99%/95% UTL of 1.6×10^{-12} µCi/mL$_{air}$. Results are similar between the sampling locations. All samples were significantly below the DOE DCS for tritium in air (as water vapor) of 1.3×10^{-7} µCi/mL$_{air}$. Results are shown in Table C-4, Appendix C.

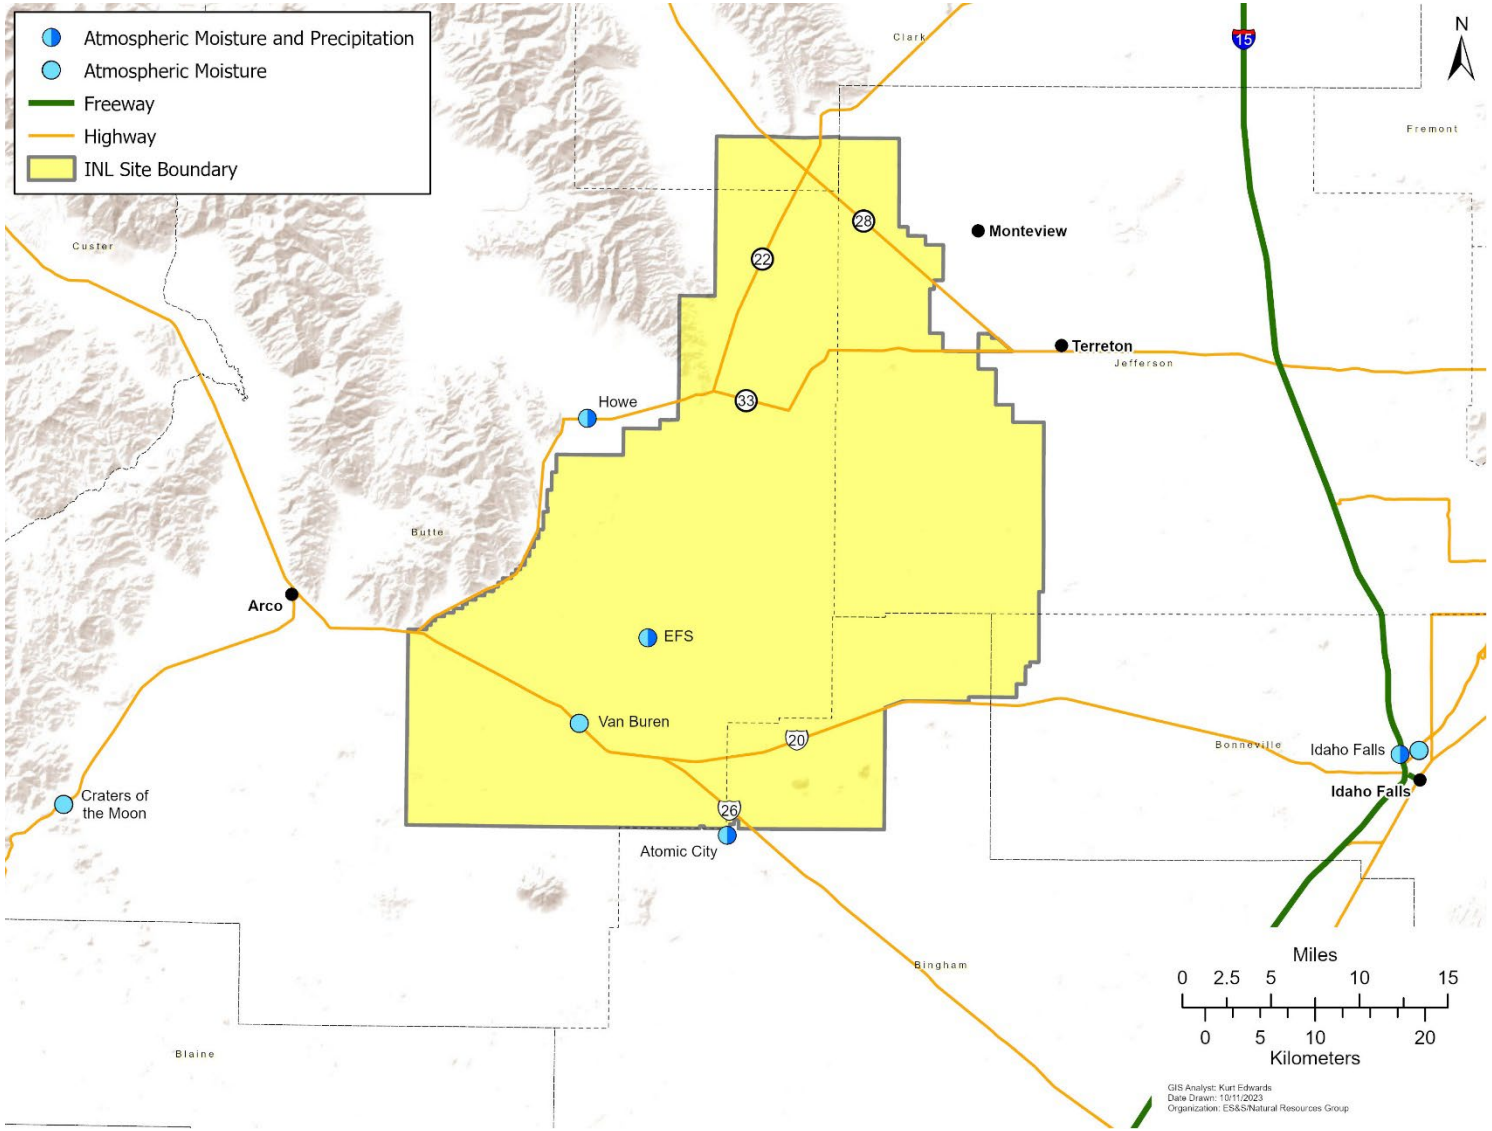

Figure 11. Atmospheric moisture and precipitation monitoring locations.

4. Precipitation and Drinking Water Sampling

4.1 Precipitation Sampling

Precipitation samples are gathered when enough precipitation occurs to allow for the collection of the minimum sample volume of approximately 50 mL. Samples are taken of monthly composites from Idaho Falls, and weekly (when available) from the EFS (onsite), Atomic City and Howe (boundary) (Figure 11). These are the same locations where atmospheric moisture samples are collected. Precipitation samples are analyzed for tritium. Storm events in the second quarter of 2023 produced sufficient amounts of precipitation to yield 23 samples.

Tritium was measured below the 3s values in all 23 samples. These results are listed in Table C-5 (Appendix C). Low levels of tritium exist in the environment at all times as a result of cosmic ray reactions with water molecules in the upper atmosphere. Long-term data collected around the globe since 1961 by the International Atomic Energy Agency suggest that tritium levels have steadily decreased since the Nuclear Test Ban Treaty in 1963 and are close to their pre-nuclear test values (Cauquoin et al. 2015) and that there are no longer remnants of fallout from weapons testing.

4.2 Drinking and Surface Water Sampling

Drinking water samples were collected at nine locations (including a control). A duplicate sample was also collected. Surface water samples were collected at three Thousand Springs locations. All samples were analyzed for gross alpha, gross beta, and tritium. Results are listed in Table C-6 of Appendix C.

Gross alpha activity was detected in two of the ten drinking water samples (Rest Area and Shoshone) and in none of the three surface water samples. The highest reported gross alpha value for drinking water was (1.73 ± 0.49) pCi/L in the drinking water sample from Shoshone.

Gross beta activity was detected in eight of the ten drinking water samples (all except the control and Howe), and in all three of the surface water samples. All concentrations were similar to previous results from drinking and surface water sampling. Natural levels of radioactive decay products of thorium and uranium exist in the Snake River Plain Aquifer and are the likely source of the measured concentrations. The highest reported gross beta value for drinking water was (5.45 ± 0.54) pCi/L in the duplicate sample collected from Minidoka. The highest reported gross beta result for surface water was (7.97 ± 0.61) pCi/L in the sample collected from Alpheus Spring. Tritium was detected in two drinking water samples (Howe and control) and two surface water samples (Alpheus Spring and Clear Springs).

5. Agricultural Products and Wildlife

Another potential pathway for contaminants to reach humans is through the food chain. The INL contractor samples multiple agricultural products and game animals from around the INL Site and southeast Idaho. Specifically, milk, alfalfa, grain, potatoes, lettuce, large game animals, and waterfowl are sampled. Milk is sampled throughout the year. Large game animals are sampled whenever they are killed onsite from vehicle collisions. Alfalfa is collected during the second quarter, lettuce and grain are sampled during the fourth quarter, while potatoes are collected during the third or fourth quarter. Waterfowl are collected in either the third or fourth quarter. See Table A-1, Appendix A, for a sampling schedule. This section discusses results from milk and alfalfa available during the second quarter of 2023.

5.1 Milk Sampling

Milk samples were collected weekly at Rigby and Terreton. Monthly samples were collected at six locations around the INL Site (Figure 12) during the second quarter of 2023. In addition to the regional locations, commercially-available organic milk (from Colorado) was purchased as a control sample each month. All samples were analyzed for gamma emitting radionuclides, with particular emphasis on ^{131}I.

Iodine-131 was not detected in any weekly or monthly samples during the second quarter. A sample collected in Monteview on April 18, 2023, resulted in a Cesium-137 value that was slightly greater than 3s. Review of the ^{137}Cs result and uncertainty suggest the data could be a false positive. The result is well below the DCS for ^{137}Cs in milk (2.7×10^4 pCi/L). No other human-made gamma-emitting radionuclides were found either. Data for ^{131}I and ^{137}Cs in milk samples are listed in Appendix C, Table C-7.

Strontium-90 was not detected in any of the milk samples collected during the second quarter of 2023. Data for ^{90}Sr in milk samples are listed in Appendix C, Table C-8.

Tritium was detected in the control sample collected from Colorado. All results were similar to those previously measured and similar to those found in other liquid media like precipitation. The result was well below the DCS for tritium in milk (1.2×10^7 pCi/L). Data for tritium in milk samples are listed in Appendix C, Table C-8.

5.2 Alfalfa Sampling

Alfalfa results were not available at the time of report preparation. They will be included in the third quarter 2023 report.

5.3 Large Game Animal Sampling

One deer was available for sampling during the second quarter of 2023. Muscle, liver, and thyroid samples were collected from the animal. No human-made gamma-emitting radionuclides were detected in any of the tissues. Results for the tissue samples are listed in Appendix C, Table C-9.

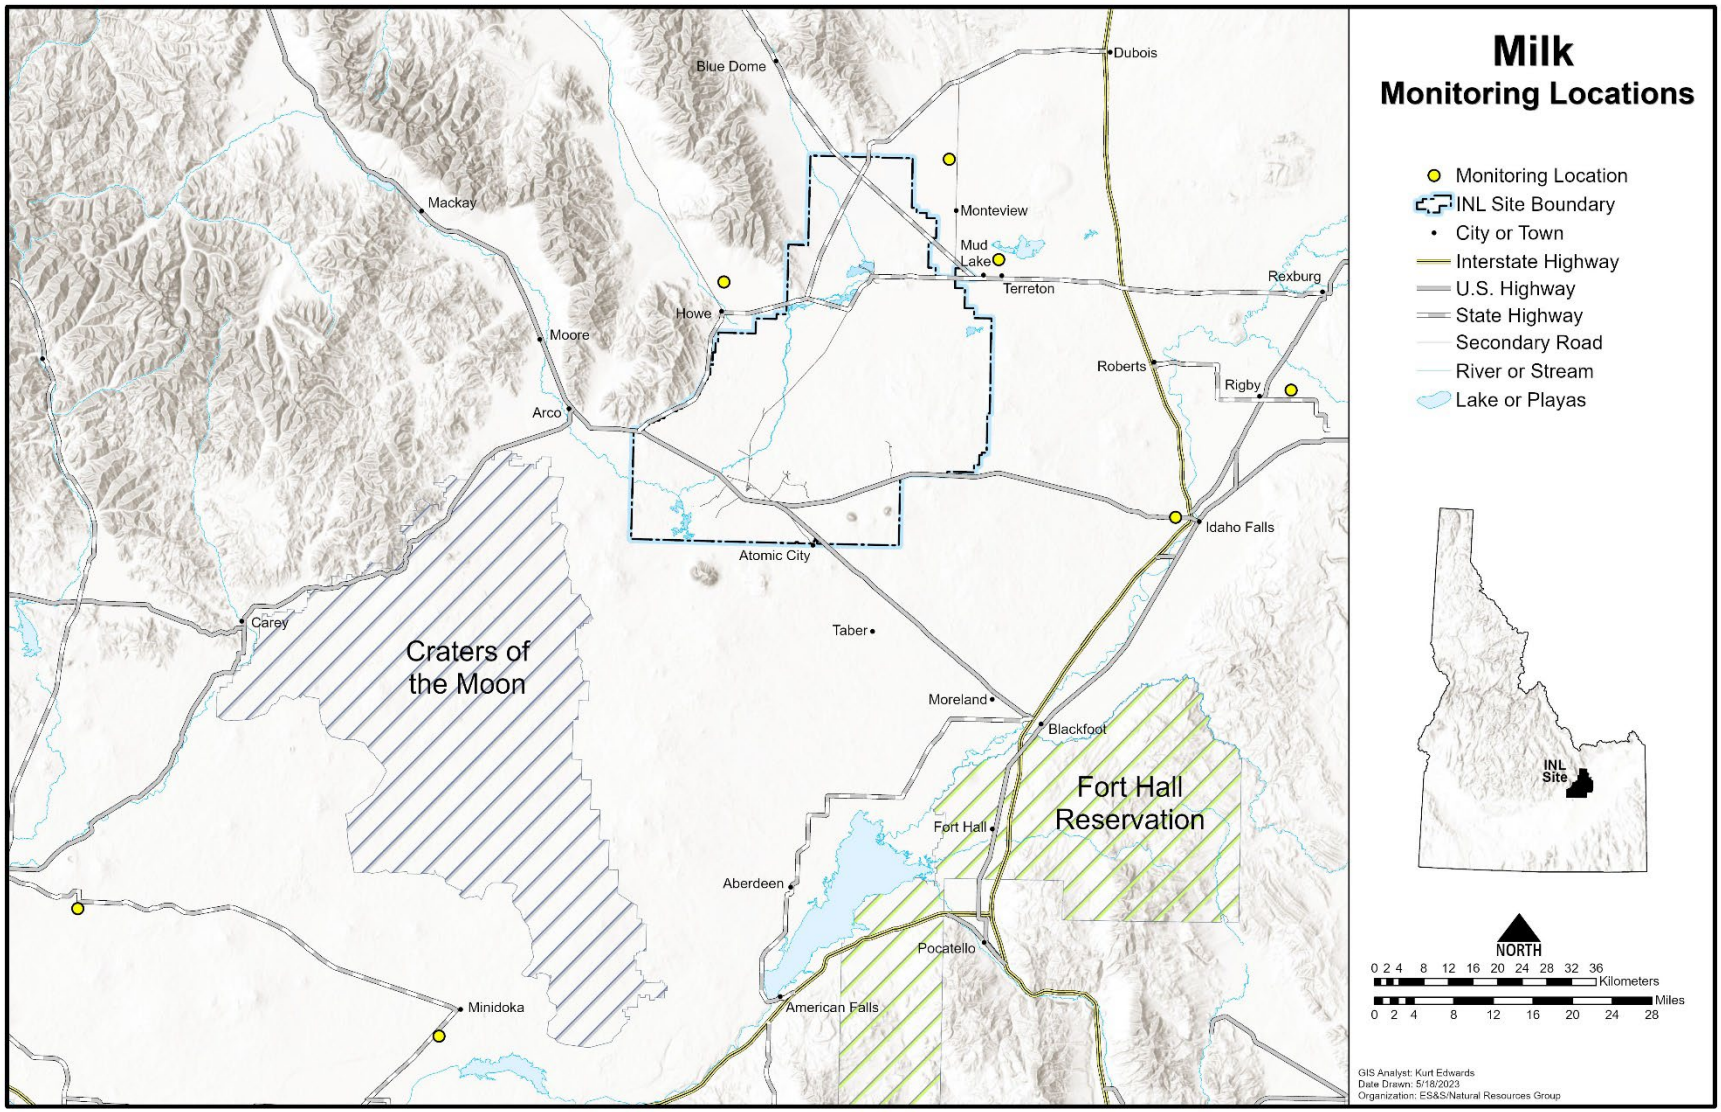

Figure 12. INL contractor milk monitoring locations.

6. Environmental Radiation

An array of optically stimulated luminescent dosimeters (OSLDs) are distributed throughout the Eastern Snake River Plain and on the INL Site (Figure 13) to monitor for environmental radiation. In addition, neutron dose monitoring is conducted around INL facilities and buildings where neutron radiation may be present.

OSLD results from dosimeters collected during the second quarter of 2023 are displayed in Appendix C, Table C-10. Results are presented in dose units of millirem (mrem). Similar to the low-volume air results the environmental dosimeter locations are also divided into onsite, boundary and offsite groupings. The onsite OSLD values ranged from 43.2 mrem at IF-IDA O-38 to 296.6 mrem at EBR I O-3, with an overall average of 66.9 mrem, which also equates to 0.37 mrem per day. The boundary OSLD values ranged from 45.0 mrem at Blue Dome E-1 to 72.8 mrem at RRL5 O-1, with an overall average of 56.57 mrem. This equates to an average daily dose of 0.31 mrem. Offsite results varied from 48.2 mrem at Craters of the Moon O-7 to 67.0 mrem at Sugar City E-1. The offsite average was 55.58 mrem, which also equates to 0.31 mrem per day. The reported results for dosimeters collected during the second quarter 2023 were primarily below the background UTL values. Table 1 lists the locations that exceeded the background level UTL.

The facility dosimeters that exceeded the background level UTL are located at INTEC [listed as Idaho Chemical Processing Plant (ICPP)], and the Advanced Test Reactor (ATR) Complex [listed as Test Reactor Area (TRA)] (Table 1). The TRA O-10 result is only slightly over the UTL. The ICPP result presented in Table 1 appears to follow a pattern of elevated measurements observed at those locations. The location has consistently shown higher results when compared to other locations at INTEC. The UTL exceedances for locations near INTEC, and ATR Complex are most likely due to operations in those areas. All environmental dosimetry results were provided to the INL Radiation Control Department for their consideration.

Table 1. Dosimetry location above background level UTL.

Location	***Ambient dose (mrem)***	***Background UTL (mrem)***
ICPP O-15	177.6	146.9
TRA O-10	130.7	121.0

All neutron dosimeters collected during second quarter 2023 were reported as ‘M’ which denotes the dose equivalents are below the minimum measurable quantity of 10 mrem. The background level for neutron dose is zero and the current dosimeters have a detection limit of 10 mrem. Any neutron dose measured is considered present due to sources inside the building. The INL contractor follows the recommendations of the manufacturer to prevent environmental damage to the neutron dosimetry by wrapping each in aluminum foil. To keep the foil intact, the dosimeter is inserted into an ultraviolet protective cloth pouch when deployed.

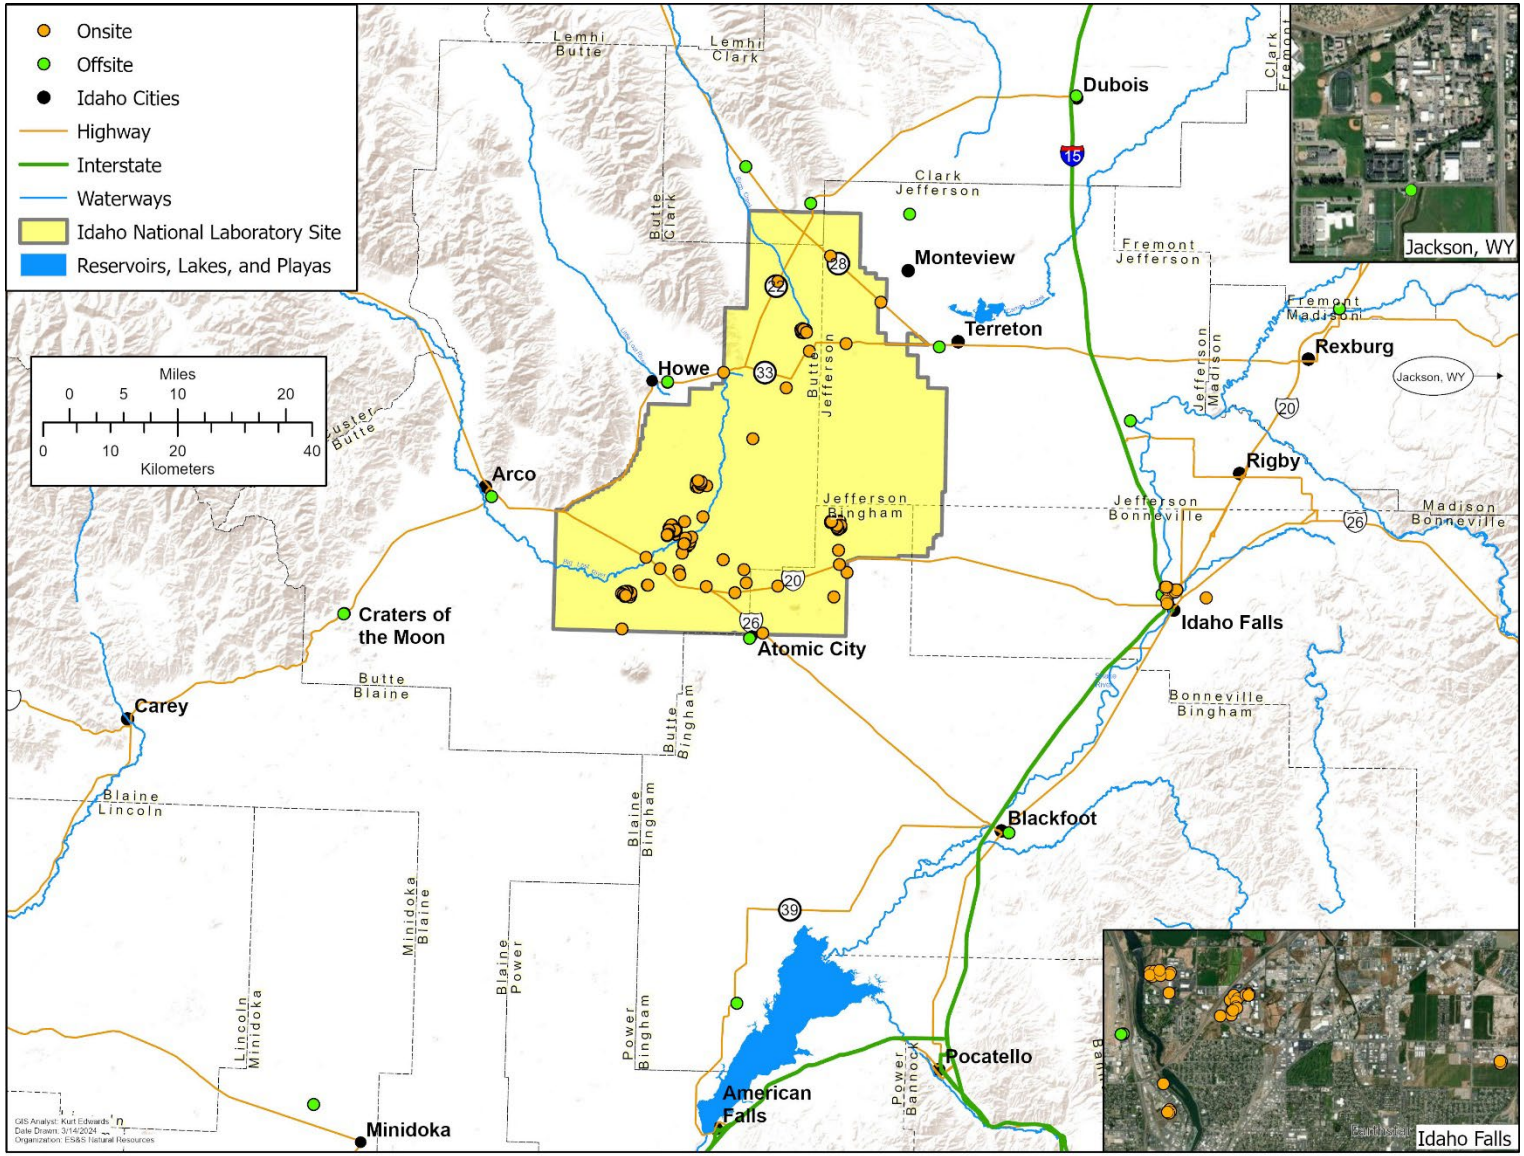

Figure 13. INL contractor OSLD locations.

7. Quality Assurance

Quality assurance consists of planned and systematic activities that give confidence in environmental surveillance program results (NCRP 2012). Environmental surveillance programs should provide data of known quality for the assessments and decisions being made. Quality assurance and quality control programs were maintained by the INL contractor and laboratories performing environmental analyses.

In addition to the quality assurance processes implemented by the INL contractor, the laboratories also utilize trained personnel, procedures, and quality assurance processes to ensure quality data. Data quality reviews were performed by the laboratory and any unusual conditions were addressed and identified in the case narrative prior to reporting to INL.

Field sampling elements, laboratory measurements, and quality control samples were reviewed and evaluated by the INL contractor laboratories. Results are summarized in Section 7.2-7.3. Together this information was used to assess the quality of data provided to the INL contractor, and to follow-up and/or conduct a corrective action to improve processes when necessary. This multi-faceted approach to quality assurance and quality control added value to the INL contractor's monitoring program by providing confidence that all laboratory data reported in this report are reliable and of acceptable quality.

The INL contractor Quality Assurance Program consists of five ongoing tasks which measure: (1) method uncertainty; (2) data completeness; (3) data accuracy, using spike, performance evaluation and laboratory control samples; (4) data precision, using split samples, duplicate samples and recounts; and (5) presence of contamination in samples, using blanks.

Sample results are compared to criteria described in the *Environmental Monitoring Services Quality Assurance Project Plan* (INL 2022).

Assessments of the INL contractor data quality are achieved through analysis of spike, performance evaluation, and duplicate samples; through sample recounts; through analysis of blank samples; and through comparison of sample results to established method quality objectives.

7.1 Inter-laboratory Program Performance Testing Evaluations

Laboratories used for routine analyses of radionuclides in environmental media were selected by the INL contractor based on a laboratory's capabilities to meet program objectives, such as the ability to meet required detection levels, and past results in performance testing (PT) programs. The DOE Consolidated Audit Program – Accreditation Program (DOECAP-AP) (comprised of third-party accreditation bodies) issues an annual accreditation certificate to laboratories seeking and maintaining accreditation. The rigorous accreditation process reviews each method, media, and analyte analyzed at the laboratory. An annual audit is performed to evaluate a laboratory's technical capability and competence, along with their proficiency in complying with DOE quality assurance requirements as outlined in the Quality Systems Manual (QSM 2021).

Similar to DOECAP-AP, DOE Laboratory Accreditation Program (DOELAP) is responsible for implementing performance standards for DOE contractor external dosimetry program through periodic performance testing and on-site program assessments.

INL contracts with analytical laboratories who participate in PT programs accredited to ISO 17043 as outlined in the Quality Systems Manual (QSM 2021). The analytical laboratory is responsible for reviewing their PT results and correcting potential quality concerns identified by the PT provider. Analytical results from these PT providers are then compared to performance evaluations (PE) results for each media and analyte tested. DOECAP accreditation is obtained by achieving a history of two successful studies (acceptable scores) out of the most recent three attempts. Second quarter 2023 PT participation and results are listed below.

GEL Laboratories, LLC
GEL is accredited through DOECAP-AP and participated in PT through Environmental Resource Associates (ERA) during the second quarter. GEL had acceptable results for analytes, methods, and media of interest to the INL contractor.

Landauer
Landauer is accredited through the DOE Laboratory Accreditation Program. Accreditation must be renewed on a triennial basis following periodic performance testing and on-site program assessments.

7.2 Quality Control Sample Program

The INL contractor sends quality control samples to laboratories along with routine environmental samples to be analyzed in tandem. The samples are prepared in a way that the quality control samples are analogous to the field samples. The laboratory is not aware of which samples are blanks, duplicates or PE samples. Blanks, duplicate/replicate samples and PE samples for the second quarter are discussed below.

7.2.1 Blanks

The INL contractor submits field blanks along with the regular samples to test for the introduction of contamination during the process of field collection, laboratory preparation, and laboratory analysis. In the event a data quality or trending issue is identified, the concern will be documented in the Issues Management System to track resolutions and/or corrective actions.

No concerns were identified in blanks that would indicate data quality or trending issues with sampling, handling, shipment, or analysis by the laboratory contributed to the actual sample results. Second quarter 2023 blanks are discussed below.

GEL Laboratories, LLC
A total of 43 analytes were analyzed by GEL in various media. The media analyzed included: air filters, quarterly air filter composites, atmospheric moisture, and milk.

Idaho State University-Environmental Assessment Laboratory
A total of 48 analytes were analyzed by ISU-EAL in various media. The media analyzed included: air filters, charcoal cartridges, quarterly air filter composites, milk, atmospheric moisture, and precipitation.

7.2.2 Duplicate/Replicate Samples

The INL contractor submits field duplicate/replicate samples with the regular samples to assess field collection, homogeneity, reproducibility, laboratory preparation, laboratory analysis, and precision. In the event a data quality or trending issue is identified, the concern will be documented in the Issues Management System to track resolutions and/or corrective actions.

No concerns were identified in duplicate/replicates that would indicate data quality or trending issues with sampling, handling, shipment, homogeneity, reproducibility, or preparation and analysis by the laboratory contributed to the actual sample results. Second quarter 2023 duplicate/replicate samples are discussed below.

GEL Laboratories, LLC
A total of 108 analytes were analyzed by GEL Laboratories. The media analyzed included air filters and quarterly air filter composite samples.

Idaho State University-Environmental Assessment Laboratory

A total of 48 analytes were analyzed by ISU-EAL in various media. The media analyzed included: air filters, charcoal cartridges, quarterly air filter composites, milk, and drinking water.

7.2.3 Performance Evaluation (PE) Samples

PE samples are prepared samples that contain known values of analyte(s) of interest to the specific project, INL Site contractor program, or laboratory. PE samples are used to assist in improving accuracy of laboratory data by evaluating the analytical method (e.g., new media, new analyte, or adverse trends in PT or PE samples). The samples are matched as closely as possible to the specific media, analytes of interest, and expected concentration or activity levels appropriate for the specific project, program, or use in decision-making. In some cases, the PE sample matrix may differ from the field samples (i.e., using deionized water with a known amount of analyte to simulate an atmospheric moisture sample). The PE samples are generally submitted with batches of field samples, so they are processed simultaneously in the laboratory. In the event a data quality or trending issue is identified, the concern will be documented in INL's Issues Management System for tracking responses from the laboratory on the resolutions and/or corrective actions. These concerns provide for an opportunity for the INL contractor to work with the laboratory to fine tune methods, processes, and procedures that will lead to improved accuracy of the data.

In addition to the INL contractor PE program, GEL and ISU-EAL laboratories participate in Mixed Analyte Performance Evaluation Program (MAPEP). MAPEP provides quality assurance oversight for environmental analytical services by performing semiannual performance evaluations of commercial laboratories. These results are then compared with the INL contractor's internal PE results.

Idaho State University-Environmental Assessment Laboratory

Idaho State University-Environmental Assessment Laboratory (ISU-EAL) participated in MAPEP Series 48 during second quarter and had overall acceptable results for the analytes, methods, and media of concern to the INL contractor.

A total of 10 PE analytes for milk and drinking water were analyzed by ISU-EAL for gross alpha, gross beta, low energy beta emitter (tritium), and gamma emitters. All low energy beta and gamma emitters, and gross beta PE samples received an agreement evaluation.

A nonagreement evaluation was identified for gross alpha in drinking water and was a first-time occurrence. The INL contractor requested ISU-EAL to follow-up on the nonagreement. The ISU-EAL investigation identified that the sample was not acidified. The INL contractor requested a For-Cause Review to look at other samples in the group. ISU-EAL identified that the laboratory technician had acidified the other samples prior to analysis. The INL contractor reviewed all sample results and the results were comparable to historical values.

GEL Laboratories, LLC

GEL participated in MAPEP Series 48 during the second quarter and had overall acceptable results for the analytes, methods, and media of concern to the INL contractor.

A total of 10 PE analytes for air filter composites and milk were analyzed by GEL for gamma emitters, alpha emitters, and a beta emitter. All the alpha and beta emitter PE samples received an agreement evaluation.

A nonagreement evaluation was identified for ^{65}Zn in an air filter composite PE sample. Upon review of the nonagreement, it was noted that the INL contractor incorrectly entered the sample collection date into the PE provider data entry system resulting in a nonagreement. This caused an error in the analyte decay

result for this short half-life analyte. As a corrective action, the INL contractor will revise the air procedure to include independent verification of PE results prior to being submitted. Even with the corrected analyte decay, results were still outside the PE criteria. The laboratory was contacted and a request was made to review the ^{65}Zn nonagreement. The laboratory's review was inconclusive. The INL contractor reviewed previous PE and ERA PT air filter composites results and all analytes of interest for the composites were in agreement. This is a first occurrence for ^{65}Zn and not indicative of a trend.

Landauer

A total of four PE analytes for direct radiation were analyzed by Landauer. All analytes received an agreement evaluation.

7.3 Invalid Samples

The sampler located at INTEC (NE Corner) was inoperable for several weeks due to a power outage. As a result, samples were invalid as indicated in Table C-1 and C-2 of Appendix C. The composite for this location included two valid air filter samples.

Eight samples (air filters and charcoals) were deemed invalid due to power outages at Blue Dome, FAA Tower, MFC North, and MFC South (Table C-1 and C-2).

Two samples (air filter and charcoal) were deemed invalid due to wildlife pulling the air tube off the sampler head at Craters of the Moon (Table C-1 and C-2).

Appendix B
Summary of MDCs and DCSs

Table B-1. Summary of approximate MDC for radiological analyses performed during second quarter 2023.

Sample Type	Analysis	Average MDC[a]	DCS[b]
Air (particulate filter)[e]	Gross alpha	7.2×10^{-16} µCi/mL	1.1×10^{-13} µCi/ml[c]
	Gross beta	1.3×10^{-15} µCi/mL	9.6×10^{-12} µCi/ml[d]
	^{137}Cs	2.1×10^{-16} µCi/mL	3.8×10^{-11} µCi/ml
	^{90}Sr	1.3×10^{-16} µCi/mL	9.6×10^{-12} µCi/ml
	^{241}Am	1.3×10^{-17} µCi/mL	1.3×10^{-13} µCi/ml
	^{238}Pu	1.2×10^{-17} µCi/mL	1.2×10^{-13} µCi/ml
	$^{239/240}$Pu	1.1×10^{-17} µCi/mL	1.1×10^{-13} µCi/ml
	$^{233/234}$U	3.2×10^{-17} µCi/mL	1.6×10^{-13} µCi/ml
	^{238}U	2.1×10^{-17} µCi/mL	1.8×10^{-13} µCi/ml
Air (charcoal cartridge)[e]	^{131}I	3.1×10^{-13} µCi/mL	4.5×10^{-10} µCi/ml
Air (atmospheric moisture)	^{3}H	2.0×10^{-12} µCi/mL$_{air}$	1.3×10^{-7} µCi/ml$_{air}$
Air (precipitation)	^{3}H	93 pCi/L	2.6×10^{6} pCi/L
Milk	^{131}I	0.4 pCi/L	1.0×10^{4} pCi/L
	^{137}Cs	0.6 pCi/L	2.7×10^{4} pCi/L
	^{3}H	99 pCi/L	1.2×10^{7} pCi/L
	^{90}Sr	0.3 pCi/L	5.8×10^{3} pCi/L

a. The MDC is an estimate of the concentration of radioactivity in a given sample type that can be identified with a 95% level of confidence. MDCs are calculated and reported by the laboratories based on actual INL contractor sample results following analysis.
b. DCSs, set by the DOE, represent reference values for radiation exposure. They are based on a radiation dose of 100 mrem/yr for exposure through a particular exposure mode such as direct exposure, inhalation, or ingestion of water.
c. Based on the most restrictive human-made alpha emitter (^{239}Pu).
d. Based on the most restrictive human-made beta emitter (^{90}Sr).
e. The approximate MDC for air is based on an average filtered air volume (pressure corrected) of 445 m^3/week.

a. Kruskal Wallis test statistic calculated using mean ranks. This test assumes H is approximately distributed as χ^2.
b. A p-value (probability value) greater than 0.05 signifies no statistical difference between data groups. Any values below 0.05 are indicated in red.

Table D-2. Results of multiple comparisons of gross alpha results between locations during the second quarter. A 'p' value greater than 0.05 signifies no statistical difference between data groups. Any values below 0.05 are indicated in red. 'R' represents the average rank for each location.

Multiple Comparisons p values (2-tailed); Coded result (x10-15) (2nd-Qtr-2023_Air_alpha_beta in 2nd-Qtr-23-LVf)
Independent (grouping) variable: Sample Location
Kruskal-Wallis test: H (32, N= 413) =25.56565 p =.7825
Include condition: v8='gross alpha'

Table D-3. Results of multiple comparisons of gross beta results between locations during the second quarter. A 'p' value greater than 0.05 signifies no statistical difference between data groups. Any values below 0.05 are indicated in red. 'R' represents the average rank for each location.

Multiple Comparisons p values (2-tailed); Coded result (x10-15) (2nd-Qtr-2023_Air_alpha_beta in 2nd-Qtr-23-LVf)
Independent (grouping) variable: Sample Location
Kruskal-Wallis test: H (32, N= 413) =25.56565 p =.7825
Include condition: v8='gross alpha'
