Abstract. With the electric vehicle (EV) market expansion and the energy sector's shift towards electrification, the demand for battery metals, including lithium (Li), cobalt (Co), and nickel (Ni), is set to surpass supply. A critical knowledge gap exists in the purity standards for battery precursors and the impact of impurities on battery performance. Addressing this, our study employs a Deep Machine Learning (DL) based multi-objective optimization approach to interpret the relationship between metal impurities in domestic battery resources and their effects on battery performance. We analyze experimental data from Li-ion batteries with NMC (Nickel-Manganese-Cobalt oxide) cathodes over 1000 cycles, representing approximately ~6-8 months of operation, to establish a baseline of performance without impurities. Leveraging this data, we develop a Physics-Informed Deep Learning (PIDL) framework to extend our findings to cases that include metal impurities (e.g., Fe, Cu, Al) ranging from (0.001 - 0.01) %, respectively. By incorporating physics-based features, our PIDL model can accurately estimate the performance of NMC cathodes doped with various metal impurities to provide rapid design decisions. This research paves the way for informed decisions in Li-ion battery material design and optimization, ensuring the sustainable growth of the EV market and the broader energy sector.

**Keywords:** Li-ion battery, NMC(nickel-manganese-cobalt oxide) cathodes, metal impurities, machine learning, electric vehicle(EV)

#### Physical Model, Methodology and Governing Equations Data-driven Anode(-ve) NMC Cathode(+ve) Physics-informed neuron= n $\frac{\partial c_{s,j}(r,t)}{\partial t} = \frac{D_{s,j}}{r^2} \frac{\partial}{\partial r} \left[ r^2 \frac{\partial c_{s,j}(r,t)}{\partial r} \right]$ (i) $D_{s,j} \frac{\partial c_{s,j}(r,t)}{\partial t} = 0$ $MSE_{DDM}$ (ii) $D_{s,j} \frac{\partial c_{s,j}(r,t)}{\partial t} = -J_j$ layer n $C_{s,n}(r,t)$ $C_{s,p}(r,t)$ **Electrolyte** Fick's law of diffusion layer 1 $MSE = MSE_{DDM} + MSE_{\theta}$ Considering intercalation reaction (Butler-Volmer expression) Predicted $MSE < \delta$ $J_{j} = \frac{i_{0,j}}{F} \left[ \exp \left( \frac{\alpha_{a,j} F \eta_{j}}{RT} - \exp \left( \frac{(\alpha_{a,j} - 1) F \eta_{j}}{RT} \right) \right) \right]$ $i_{0,j} = i_{0,j}{}^{0} c_{e}{}^{\alpha_{a,j}} \left( C_{s,max,j} - C_{s,j}|_{r=R_{s,j}} \right)^{\alpha_{a,j}} \left( c_{s,j}|_{r=R_{s,j}} \right)^{(1-\alpha_{a,j})}$ battery throughput Fig 1. Schematic of a Li-ion battery with impurity doped NMC cathode where Impurity metals Nominal capacity \* Roundtrip efficiency \* depth of discharge \* Battery cycle life density & kinetic $\eta_j = \phi_{s,j} - \phi_e - U_{OCP,j} \left( c_{s,j} |_{r=R_{s,j}} \right)$ are – Fe, Cu and Al overpotential

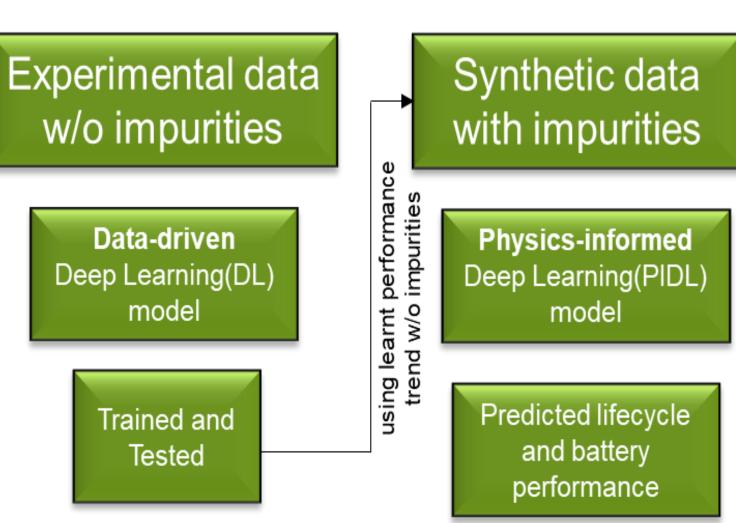

## **Data Generation**

- $\square$  Cathode type: NMC622 (0.6 Ni : 0.2 Mn : 0.2  $CoO_2$ )
- ☐ Experimental Data <u>without Impurities</u>:
- Run time for 1 battery for lifetime of 750-1100 cycles is around 6-8 months
- Datasets (training features) mentioned in Table 1 have been captured and obtained from **battery-pro** software
- Battery throughput i.e., battery performance is calculated using eqn. (1), below

 $Battery\ throughput=Nominal\ capacity*Roundtrip\ efficiency*depth\ of\ discharge*Battery\ cycle\ life$ 

- ☐ Synthetic datasets with impurities
- Impurity metals: Iron(Fe), Copper(Cu), Aluminum(Al)
- Impurity percentages for each metal 0.001%, 0.005%, 0.01%
- Based on the information obtained for battery performance w/o impurities, synthetic datasets have been generated to train a PIDL model solving the governing equations and boundary conditions.
- To solve the physics-based equations, we obtain the required "features" stated in Table 2. based on literature datasets.

# **Training and Testing**

## **Results and Discussions**

# 24 Thermal expansion co-efficient 11 S.Capacity (Ah/g) 26 volumetric capacity of impurities (Ah/cm<sup>3</sup>) 12 Power (W) 27 Capacity change based on Cathode dimension

physics-based features for training both DL and

- been obtained from experimental data and used in DL model.
- Physics-based features (no.19-44) have been added to enhance training in PIDL model.

# Conclusion

- **Accelerated prediction** Our developed PIDL framework can precisely predict the overall lifecycle of a Li-ion battery with impurity doped NMC cathodes in seconds.
- Design decision It can help us to achieve quick and informed design decision to optimize battery performance.
- Cost and Time PIDL models can significantly reduce costs by reducing experimental timeline for a single battery from ~6-8 months to a few seconds and by minimizing expenses involved in refining metallic materials.

### **Obstacles and Future Direction**

- Insufficient training datasets Due to prolonged duration of our experiments, we lacked sufficient training data to effectively train our deep learning model. Hence, we created synthetic placeholder datasets to evaluate the effect of impurities for PIDL model development, training and testing.
- Future direction –
- Use **electrochemical impedance spectroscopy** data for solving the governing equations for the PIDL model.
- Validate and optimize our model with each new acquisition of experimental data.
- Extend the performance prediction for other metal impurities (e.g., Cu, Al, Mg or combination of metal impurities)
- Use the model for inverse design and multi-objective optimization (e.g., cost analysis)
