TPMS Hydraulic Performance - Experiment and CFD

Intern: Brett Prussack
Mentor: Austen Fradeneck
University: University of Wisconsin - Madison

Benchmarking Triply Periodic Minimal Surface (TPMS) lattices with CFD

Motivation

- Nuclear fuel is traditionally confined to plates, cylinders, and spheres
 - Easily manufacturable
 - Not ideal for heat removal
- Advanced manufacturing allows complex, bio-inspired geometries to be studied in the context of nuclear fuel
 - Triply periodic minimal surfaces (TPMS)
 - High surface area-volume ratio
- Validation between experiments and models are critical

Meshing / Grid Convergence

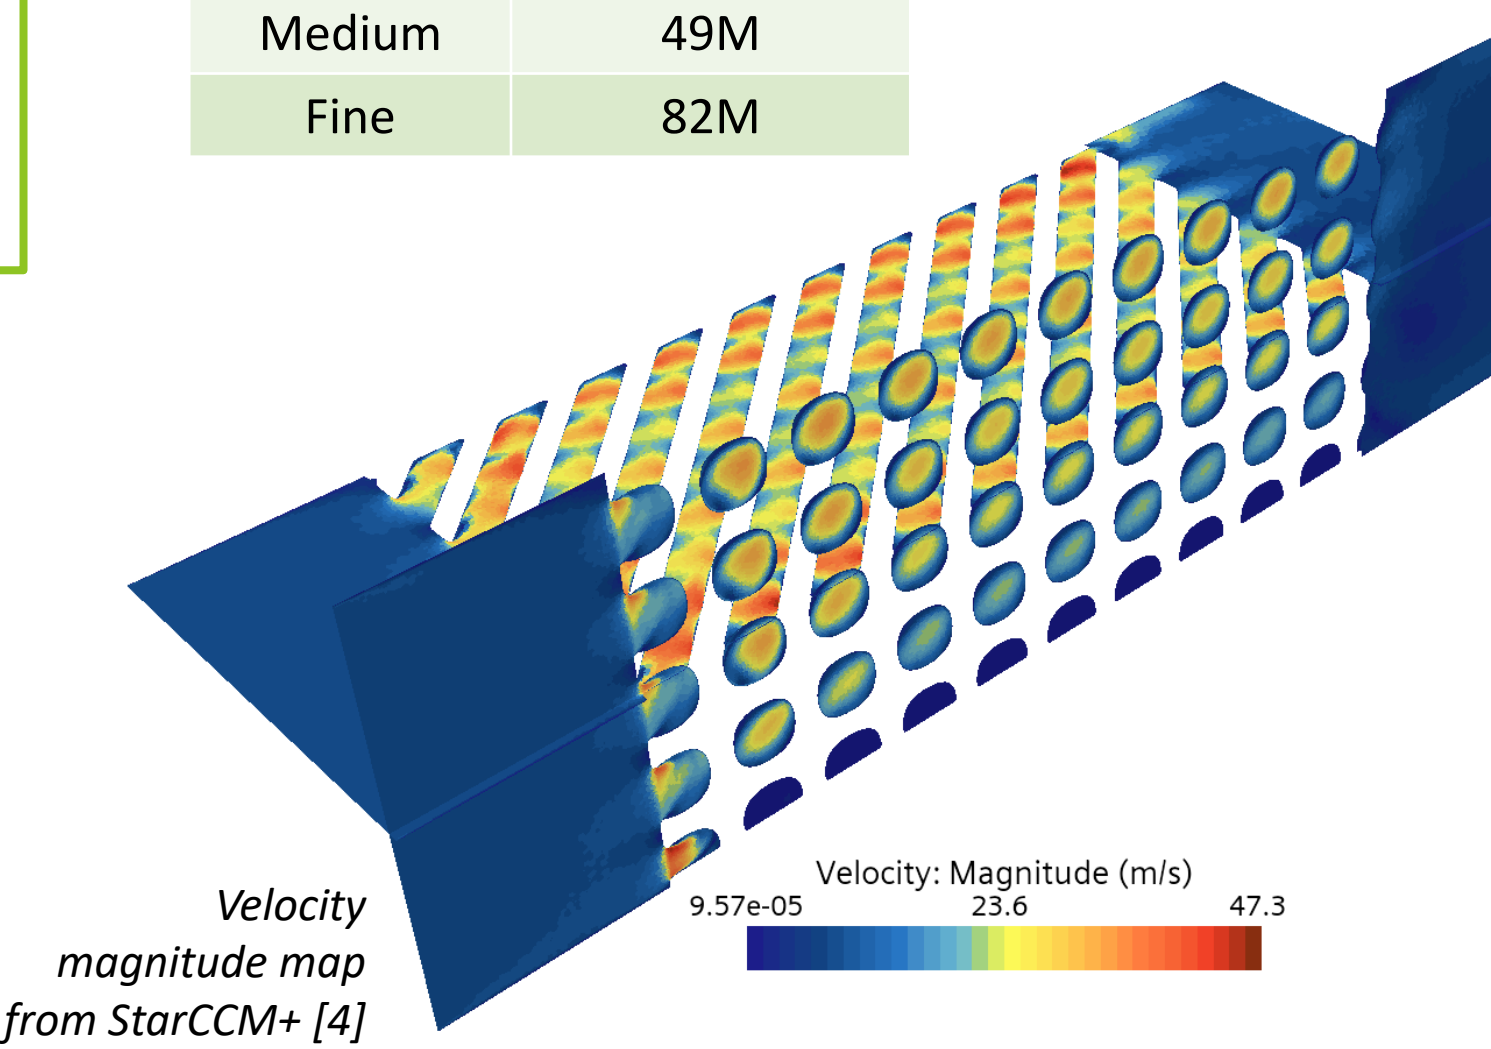

Three meshes studied to confirm grid independence

Mesh	Elements
Coarse	1.5 M
Medium	49M
Fine	82M

Grid independence obtained for meshes with 150-200 elements / mm³

Reynolds Number	Uncertainty (psi)	Uncertainty (%)
1000	0.00043	0.03
2000	0.002	0.052
3500	0.01	0.26

Experiment Design and Goals

- Target several key behaviors relevant to reactor core designers:
 - Length effect
 - Unit cell effect
 - Bypass effect
 - Wall effect
 - Tortuosity Effect
 - Truncation Effect
 - Rotation effect
- 9 TPMS lattices were printed, tested, and simulated in StarCCM+ [4]

Experiment / Simulation Agreement

- Experiment and simulation have $\geq 50\%$ error

Simulation trends that agree with experiments:

- Linear length scaling
- Wall effect
- Unit cell effect
- Bypass effect
- Truncation effect
- Tortuosity effect

Simulation trends that disagree with experiment:

- Rotation

Troubleshooting Steps:

- Grid convergence
- Turbulence models
- Fluid properties
- Experiment error
- Simulation error

Experimental Results

- Length Effect:**
 ΔP scales linearly with length beyond 5UC
- Unit Cell Effect:**
Different unit cells do not collapse w/ Reynolds #
- Bypass effect:**
1mm bypass results in 25% reduction in ΔP

- Wall effect:**
Wall friction effect is not significant beyond 2UC in width
- Tortuosity effect:**
Axial stretching along the flow direction by 2x reduces ΔP by 6x
- Rotation effect:**
A 45 rotation off the principal axis results in a 30-40% increase in ΔP
- Truncation effect:**
Entrance and exit effects are independent of the inlet geometry

Future Work

- Improve agreement between experiment and CFD
 - Explore turbulence models
- Determine mesh convergence requirements at higher Reynolds numbers
- Develop larger test loop for wider range of data
- Develop porous media model to reduce computational requirements

Acknowledgements

I'd like to thank my mentor, Dr. Austen Fradeneck, my manager, Dr. Piyush Sabharwal, and Nicolas Woolstenhulme for providing the guidance, resources, (and filament) that contributed to this work. I'd also like to thank my advisors, Mark Anderson and Greg Nellis at UW-Madison for further guidance and advice. This work was supported through the INL LDRD Program under the DOE operations office contract DE-AC07-05ID14517.
