EXECUTIVE SUMMARY

A collaboration between the Idaho National Laboratory (INL), the Kansas State University (KSU), and the French Atomic Energy Agency, Commissariat à l'Énergie Atomique et aux Energies Alternatives, (CEA), has been initiated by the Nuclear Energy Enabling Technologies (NEET) Advanced Sensors and Instrumentation (ASI) program for developing and testing High Temperature Micro-Pocket Fission Detectors (HT MPFD), which are compact fission chambers capable of simultaneously measuring thermal neutron flux, fast neutron flux and temperature within a single package for temperatures up to 800 °C.

The MPFD technology utilizes a small, multi-purpose, robust, in-core fission chambers and thermocouple. As discussed within this report, the small size, variable sensitivity, and increased accuracy of the MPFD technology represent a revolutionary improvement over current methods used to support irradiations in US Material Test Reactors (MTRs).

Previous research conducted through NEET ASI¹⁻³ has shown that the MPFD technology could be made robust and was successfully tested in a reactor core. This new project will further the MPFD technology for higher temperature regimes and other reactor applications by developing a HT MPFD suitable for temperatures up to 800 °C.

This report summarizes the research progress for this three year project. Highlights from research accomplishments include:

- A joint collaboration was initiated between INL, KSU, and CEA. Note that CEA is participating at their own expense because of interest in this unique new sensor.
- Several project meetings were held at INL and KSU to discuss the roles and responsibilities between INL, KSU, and CEA for development and deployment of the HT MPFDs.
- An updated HT MPFD design was developed.
- Selected and procured new high temperature compatible materials for HT MPFD prototype construction.
- Construction methods to support the new design were evaluated.
- Performed laboratory evaluations of construction methods of prototype HT MPFD.
- Electrical contact and fissile material plating performed.
- Updated detector electronics evaluations completed.
- Publications of MPFD technology accepted.
- Program support for HT MPFD deployments was given to Accident Tolerant Fuels (ATF) and Advanced Gas-cooled Reactor (AGR) irradiation test programs.
- An updated parallel wire HT MPFD design was developed.
- Quality approved materials for HT MPFD construction were procured by irradiation test programs for HT MPFD deployments.
- KSU improved and performed electrical contact and fissile material plating.
- KSU delivered fissile HT MPFD parts to INL for final construction of HT MPFD prototype.
- A prototype HT MPFD was constructed and analyzed at INL.
- The HT MPFD has been modeled in MCNP to optimize the amount of fissile material deposition.
- The HT MPFD has been modeled in MCNP to optimize the sensor location in the irradiation test.
- Detector amplifier electronics have been revised and tested by KSU.
- HT MPFD fissile material deposition is undergoing independent verifications at the ISU AGN-201 reactor.
- HT MPFD deployed at the CEA MINERVE for characterization of detector response.

- HT MPFD deployed at the MIT Reactor for characterization of TREAT instrumentation.
- HT MPFD deployed in a the KSU TRIGA reactor.
- TH MPFD deployed in the UW TRIGA reactor.
- HT MPFD installed in irradiation test trains for AGR 5/6/7 and ATF-2.
- US-ROK INERI project awarded to develop radiation hardened electronics for HT MPFD.
- SBIR Phase 1 awarded to commercialize HT MPFDs.
- HT MPFD under construction for deployment in TREAT cooling channels.

As documented in this report, the project has meet all planned accomplishments to develop a HT MPFD. The accomplishments of this project have allowed the HT MPFD to be deployed in other Department of Energy Office of Nuclear Energy (DOE-NE) programs for MTR irradiations. These deployments demonstrate the importance of this *NEET Enhanced Micro-Pocket Fission Detector for High Temperature Reactors* project and are significant opportunities because these irradiations could not be included in the original project scope. In addition a commercialization effort is underway to develop a strategy for larger deployments that require a high volume of MPFDs.

Enhanced Micro Pocket Fission Detector for High Temperature Reactors - FY17 Final Project Report

1. INTRODUCTION

Irradiation testing, which is often performed in harsh conditions (e.g., high flux, high temperature, etc.) in Materials Test Reactors (MTRs), is essential for evaluating the performance of new materials and fuels prior to use in commercial reactors. Accurate monitoring of these harsh conditions with compact sensors, that are less likely to disturb the conditions of interest, is necessary to quantify any degradation that occurs during irradiation.

Miniature fission chambers and thermocouples have been used in-core at research and test reactors throughout the world; however, none have been deployed in a single compact package to survive the harsh conditions that exist within many tests conducted in MTRs. Previous research conducted through Nuclear Energy Enabling Technologies (NEET) Advanced Sensors and Instrumentation (ASI) ¹⁻⁴ has shown that the Micro-Pocket Fission Detector (MPFD) technology could be made robust and was successfully tested in a reactor core. However, it was recognized that a High Temperature MPFD (HT MPFD) would be of interest to irradiation test campaigns that test materials at elevated temperatures. The following report summarizes FY17 activities completed to develop a HT MPFD capable of measuring thermal neutron flux, fast neutron flux, and temperature within a single compact sensor for temperatures up to 800 °C.

1.1. Motivation/Objective

During the last 40 to 50 years, various sensors have been developed to meet the needs of irradiation testing for materials and fuels in MTRs. Development of these sensors is an on-going process because they are continuously improved and refined to overcome operational shortcomings associated with more complicated irradiation testing requirements. Recent interest in testing to support new reactor designs can require higher temperatures, higher fluxes, or more corrosive test conditions. The next generation of sensors is under development that can survive these conditions.

In-core fission chamber design has remained relatively unchanged for decades. Improvements in performance, overall size, and operational modes have been implemented; however, all have been based on the same design that utilizes coaxial cylinders with a high pressure fill gas. These design considerations limit the robustness, lifetime, size, and operational performance of such sensors in high performance MTR environments.

The MPFD technology utilizes the same operational concept of existing fission chamber designs, but deploys different geometry, construction, materials and operational characteristics. The small design also allows two or more of these neutron detectors and a thermocouple to be co-located within a single sensor sheath such that thermal flux, fast flux, and temperature can be simultaneously measured at very near the same location in the experiment with a single penetration in the experimental pressure boundary.

The MPFD technology offers the potential for improved, high accuracy, and higher fidelity data of interest to Department of Energy office of Nuclear Energy (DOE-NE) programs. Deployment of multiple compact HT MPFDs in irradiation tests will provide much needed information for current efforts to develop and deploy high-fidelity, multi-scale, multi-physics computer codes.

1.2. Objectives of NEET ASI HT MPFD Research

Several DOE-NE programs, such as the Fuel Cycle Research and Development (FCRD), Advanced Reactor Technologies (ART), Light Water Reactor Sustainability (LWRS), Small Modular Reactors (SMR), and Next Generation Nuclear Plant (NGNP) programs, are investigating new fuels and materials for advanced and existing reactors. The NEET ASI in-pile instrumentation development activities are focused upon addressing cross-cutting needs for DOE-NE irradiation testing by providing higher fidelity, real-time data with increased accuracy and resolution from smaller, compact sensors that are less intrusive.⁵ In particular, flux sensors are required for characterizing fuel performance as a function of burnup and cladding and structural material degradation as a function of neutron exposure. The NEET ASI program initiated the HT MPFD project because it addresses this cross-cutting need by developing, fabricating, and evaluating the performance of compact multi-purpose fission chambers with integral temperature sensors that could survive up to 800 °C.

A key objective of several DOE-NE programs is to understand the performance of candidate fuels and materials during irradiation. Hence, NEET research must produce sensors able to withstand the operating conditions of interest to these DOE-NE programs. It is also important that the sensors be able to measure test parameters with the desired accuracy and resolution required by these DOE-NE programs and that the sensors be compact to minimize their impact on irradiation test data. Recognizing that DOE-NE program needs change, the NEET program holds annual reviews to ensure that projects continue to meet DOE-NE program needs. Specific details related to requirements for thermal flux, fast flux, and temperature sensors requested by DOE-NE programs for fuels and material irradiations are summarized in this section.

1.2.1. Fuel

In-situ instrumentation is desired to provide real-time data on fuel performance phenomena. Currently, drop-in or static capsule experiments only allow data to be obtained at the endpoint of an experiment. Although visual examinations and material property measurements may be made on samples at the end of the test, such measurements are subject to error because of handling and because measurements are not made under prototypic pressures, fluxes, and/or temperatures. Sensors included in such tests can only provide insights about the integral neutron fluence or peak temperatures. In-situ sensors in irradiation tests with instrumentation leads can provide data showing the evolution of particular phenomena over time.

Clearly, real-time data obtained during an irradiation are advantageous. However, it is important to understand what additional sensors are needed to obtain data with the required accuracy and resolution. As part of this NEET effort, appropriate documents were reviewed and cognizant technical experts were contacted to gain insights related to the temperature, flux levels, and fluences proposed for fuel irradiation tests. Results from this review are summarized in Table 1.

1.2.2. Materials

Using a Light Water Reactor (LWR) as an example, there are many different types of materials that makeup the construction; over 25 different metal alloys can be found within the primary and secondary systems, not to mention the concrete containment vessel, instrumentation and control, and other support facilities. Over the initial forty-year lifetime of a LWR, internal structural components may expect to see up to $\sim 10^{22}$ n/cm² in a Boiling Water Reactor (BWR) and $\sim 10^{23}$ n/cm² in a Pressurized Water Reactor (PWR) ($E > 1$ MeV), corresponding to ~ 7 dpa and 70 dpa, respectively. The neutron irradiation field can produce large property and dimensional changes in materials. Such changes occur primarily via five radiation damage processes: radiation-induced hardening and embrittlement, phase instabilities from radiation-induced or radiation-enhanced segregation and precipitation, irradiation creep, volumetric swelling from cavity formation, and high temperature helium embrittlement due to formation of helium-filled cavities on grain boundaries. Extending the service life of a reactor will increase neutron fluence and suscepti-

Table 1. Summary of desired parameters for detection during fuel irradiation tests

Parameter	Representative Peak Value ^a	Desired ^a	
		Accuracy	Spatial Resolution
Fuel Temperature	Ceramic LWR - 1400 °C	2%	1-2 cm (axially); 0.5 cm (radially)
	Ceramic SFR - 2600 °C		
	Metallic SFR - 1100 °C		
	TRISO HTGR - 1250 °C		
Cladding Temperature	Ceramic LWR - <400 °C	2%	1-2 cm (axially)
	Ceramic SFR - 650 °C

	TRISO GCFR	NA	NA
Pressure in Fuel Rod Plenum	Ceramic LWR - 5.5 MPa	5%	NA ^b
	Ceramic SFR - 8.6 MPa		
	Metallic SFR - 8.6 MPa		
	HTGR - NA		
LWR, SFR, and HTGR Fission Gas Release (amount and composition)	0-100% of inventory	10%	NA
LWR and SFR Fuel and Cladding Dimensions (includes fuel / cladding gap size); HTGR- NA	Initial Length, 1 cm	1%	NA
	Outer diameter/Strain, 0.5 cm/5-10%	0.1%	NA
	Fuel-Cladding Gap (0-0.1 mm)	0.1%	NA
LWR, SFR, and HTGR Fuel Morphology/Microstructure/ Cracking/ Constituent Redistribution	Grain size, 10 µm	5%	1-10 µm
	Swelling/Porosity, 5-20%	2%	NA
	Crack formation and growth	2%	10-100 µm
Fuel Thermal Properties	Thermal conductivity Ceramic: < 8 W/mK; Metallic: < 50 W/mK; TRISO pebble/compact: 4-12 W/mK	4%	< 1 cm (radially)
	Density (inferred from changes in length, diameter, porosity, etc.) Ceramic: < 11 g/cm ³ ; Metallic: < 50 g/cm ³ ; TRISO pebble/compact: 2.25 g/cm ^{3c}	2%	NA
Real-time Thermal and Fast Neutron Flux for Estimating Fluence and Fuel Burnup for Fuel Irradiations	Thermal neutron flux - ~1-5 x 10 ¹⁴ n/cm ² -s	1-10%	5 cm (axially)
	Fast neutron flux (E> 1 MeV) - ~1-5x10 ¹⁴ n/cm ² -s	15%	5 cm (axially)

a. Representative peak values, accuracy, and resolution are based on engineering judgement by cognizant program experts.

b. NA-Not Applicable.

c. Value dependent upon particle packing fraction and matrix.

bility to radiation damage (although new damage mechanisms are possible). Likewise, when one considers the additional conditions proposed within DOE-NE programs for NGNP and Sodium Fast Reactor (SFR) operation, material performance becomes more complex.

Currently, most material irradiations are relying on Post Irradiation Examination (PIE) to characterize material properties after an irradiation is completed. However, enhanced in-pile instrumentation offers the potential to supplement current PIE evaluations by increased accuracy, higher fidelity data since measurements are obtained at the conditions of interest. Currently-requested accuracies and resolutions for these materials are listed in Table 2.

Table 2. Summary of desired parameters for detection during materials irradiation tests

Parameter	Representative Peak Values ^{a,b}	Desired ^{a,b}	
		Accuracy	Spatial Resolution
Material Temperature Distribution	LWRS Fuel Cladding - >1200 °C	2%	1-2 cm (axially); 0.5 cm (radially)
	LWRS Vessel and Internal Materials - 500 °C		
	HTGR and LWRS high temperature alloys - 950 °C		
	HTGR Graphite - 600 to 1200 °C	± 50 °C (axially) ± 40 °C (radially)	NA
Material Dimensional Changes Due to Swelling	Initial Specimen Length, HTGR Graphite - 2.54 cm	1%	NA
	Outer diameter/Strain, LWR vessel and internal materials - 0.5 cm/5-10%	0.1%	NA
Material Morphology/ Microstructure/Cracking/ Constituent Redistribution	Grain size, LWR vessel and internal materials > 10 µm	5%	1-10 µm
	Swelling/Porosity, LWR vessel and internal materials 5-20%	2%	10-100 µm
	Crack formation and growth LWR vessel and internal materials > 10 µm	2%	10-100 µm
Material Thermal Properties	Thermal conductivity HTGR Graphite - ~80 W/m-K	4%	< 1 cm (radially)
	Thermal conductivity LWR vessel and internal materials ~50 W/m-K	5-20%	< 1 cm
	Thermal coefficient of expansion; HTGR Graphite - 5%	2%	NA ^c
	Density (estimated from changes in length, diameter, porosity, etc.) HTGR Graphite - 0.5%	0.2%	NA
Material Mechanical/Electrical Properties	Irradiation creep HTGR Graphite - 3-4%	NA	NA
	Young's modulus HTGR Graphite - 3-4%	NA	NA
	Electrical resistivity HTGR Graphite - 3-4%	NA	NA
	Poisson's ratio HTGR Graphite - 3-4%	NA	NA
	Fracture toughness, shear strength HTGR Graphite - 3-4%	NA	NA
Material Irradiation Neutron Flux for Estimating Fluence	Thermal neutron flux - $\sim 1.5 \times 10^{14}$ n/cm ² -s	1-10%	5 cm (axially)
	Fast neutron flux (E > 1 MeV) - $\sim 1.5 \times 10^{14}$ n/cm ² -s	15%	5 cm (axially)

a. Representative peak values, accuracy, and resolution are based on engineering judgement and are preliminary.

b. Only LWRS and NGNP irradiation information available for a limited number of parameters at this time.

c. NA-Not Available.

2. BACKGROUND

This section describes commonly used flux detection sensors in typical MTR irradiations. A brief overview discussing their theory of operation, basic construction, deployment considerations, data collection considerations, and basic advantages/disadvantages is given to emphasize advantages of the HT MPFD and how they uniquely address irradiation testing needs for DOE-NE irradiation testing programs.

2.1. Flux Sensors

Accurate measurement of the time-dependent neutron field, the neutron flux, and the integral exposure or the neutron fluence that a sample receives is needed in order to assess effects of neutron interactions on the samples under investigation. Some tests only require that the overall neutron fluence be known. Hence, passive methods are used to measure the neutron irradiation after the sample has been removed from the reactor. Many DOE-NE irradiation tests rely on passive neutron fluence measurement techniques. However, as discussed in Section 1, many DOE-NE programs have identified candidate new materials and fuels whose performance evaluations require high accuracy/high resolution real-time fast and thermal flux measurements. Such measurements are typically accomplished with Self-Powered Neutron Detectors (SPNDs) or fission chambers. As indicated in Table 3, there are advantages and disadvantages with each type of detector.^{6 through 8}

Table 3. Summary of advantages and disadvantages of typical flux sensors

Flux Sensor	General description	Typical characteristics	
		Advantages	Disadvantages
Flux Wires and Foils	Utilizes neutron activation of materials to emit measurable gamma-rays	Small Thermal/Fast neutron response No power source Simple/robust Easily installed	Not real time Rigorous post-analysis Integral measurement
Self Powered Neutron Detectors	Generates measurable electrical current under neutron irradiation	Real time Small Thermal neutron response No power source Simple/robust	Need calibration No fast neutron response Low sensitivity Delayed response Need electrometer
Fission Chambers	Fissionable material interactions provide measurable electrical pulses	Real time Small Thermal/fast neutron response Variable sensitivity	Need power source Fragile
Micro-Pocket Fission Detectors	Fissionable material interactions provide measurable electrical pulses	Real time Small Simple/robust Simultaneous thermal/fast neutron response with temperature measurement Variable sensitivity Low power requirements	Need power source

This section describes typical examples of each type of sensor along with their limitations in irradiation tests to emphasize the need for this project to develop HT MPFDs for use in DOE-NE irradiation test programs in higher flux US MTRs, such as steady-state reactors like the 250 MWt Advanced Test Reactor

(ATR) and the 100 MWt High Flux Isotope Reactor (HFIR). In addition, new transient irradiation testing programs are seeing new real-time instrumentation for Transient REactor Test (TREAT) reactor irradiation tests.

2.1.1. Flux Wires and Foils

Flux wires and foils are the most commonly used passive methods for local neutron activation spectrometry. A flux wire or foil is simply a material of known composition and purity that is placed in a neutron field. When placed in a neutron field, different elements (and different isotopes of the same element) interact differently with respect to the energy of the incident neutron. When the interaction product is radioactive, the resulting induced activity can be measured and correlated to the integral incident neutron exposure.⁶ This measurement and correlation can only be performed after the irradiation is complete and the flux wire or foil is removed from the reactor.

Deployment simply requires that the flux wires or foils be securely placed in the reactor in appropriate fixturing (Figure 1). Hence, they can be placed at nearly any location in the reactor. Some materials can be placed directly in contact with the reactor primary coolant, whereas other more fragile materials must be encased in low cross-section materials that don't affect their neutron exposure. Data collection requires removing the radioactive flux wires or foils from the reactor and placing them on a gamma ray detector and counting them for a specific amount of time. The counting information and material information, along with the irradiation time and the time since the end of the irradiation, can then be used to calculate the neutron flux. The advantages of this method are: very small sensors can be used; it is generally very accurate; it can be used for high and low flux levels; and it gives information about the incident neutron energy. The disadvantages are that it is not real-time and that it requires handling radioactive material.

Figure 1. Representative flux wires, flux foils and test hardware used at INL

2.1.2. Self Powered Neutron Detectors

SPNDs are a commonly used real-time method for monitoring local neutron flux. SPNDs are built using materials that become radioactive in a neutron field and produce a small current which is correlated to the neutron flux (Figure 2). SPNDs are built around a central electrode, known as an emitter, which is composed of a metal with a relatively high neutron capture cross section.⁶ Various SPND emitters and their properties are listed in Table 4. The central electrode is surrounded by an electrical insulator and an outer electrode, known as a collector. The outer electrode serves as a boundary between the reactor coolant and the emitter and insulator. The current between the emitter and collector is measured via external circuitry. It can take time for the current to build up in the SPND; hence, there is a delay time from several seconds to a few minutes before the signal is generated and stabilized. In addition, if the neutron signal is suddenly changed it may take several minutes for the signal to stabilize.

Figure 2. Representative Self-Powered Neutron Detector (SPND) and component sketch

Table 4. Typical emitters for SPNDs

SPND Emitter	Sensitivity (A/m)/[2×10^{17} neutrons/(m ² s)]	Response
Rhodium	2.4×10^{-6}	Delayed
Vanadium	1.5×10^{-7}	Delayed
Cobalt	3.4×10^{-8}	Prompt
Molybdenum	1.7×10^{-8}	Prompt
Platinum	2.6×10^{-7}	Prompt

Deployment requires a space large enough to fit the SPND, typically 1.5-6 mm in diameter, and the leads to be run from the experiment location to outside the reactor for signal processing; hence, SPNDs can only be deployed in specific experiment locations in the reactor. Data collection requires the SPNDs to be connected to sensitive low current measurement equipment. The SPNDs must be previously calibrated in a known neutron field so that the current response can be correlated to the incident neutron flux. The advantages of this method include: it is self powered; it provides near real time neutron flux measurement; and it is a robust sensor. The disadvantages include: it has delays associated with its response; it requires a large neutron flux to generate a large current; it requires a calibration; it is generally limited to thermal neutrons; and it requires signal leads from the experiment to outside the reactor.⁶

2.1.3. Fission Chambers

Fission chambers are another commonly used real-time method for monitoring local neutron flux. As shown in Figure 3, fission chambers are built using two electrodes, one has a fissile material deposit that emits fission fragments when placed in a neutron field. These fission fragments produce an instantaneous current pulse between the electrodes that have a polarization voltage applied between them. The resulting pulse is measured via external counting electronics. The space between the electrodes must have a fill gas to aid detector performance. Like SPNDs, the outer electrode serves as a boundary between the reactor coolant and the inner materials. The fissile material deposit can be chosen such that the detector is sensitive to either thermal neutrons or fast neutrons. Fission chambers can be operated in three different modes: pulse mode for low power applications that measure the individual pulses, current mode for midrange power applications where pulses are so frequent that they can't be separated and produce a continuous current, and Campbelling mode for high power applications where the variance of the signal is characterized and correlated to the incident neutron flux.⁶

Figure 3. Representative fission chamber and component sketch

Deployment requires a space large enough to fit the fission chambers, typically 1.5-150 mm diameter, and leads from the fission chamber location to outside the reactor vessel for data display and storage. Hence, fission chambers can only be deployed in specific experiment locations in the reactor and sometimes are deployed outside the reactor core for large fission chambers or to improve fission chamber lifetime. Fission chamber response is correlated to incident neutron flux by accurate measurement of the fissionable deposit mass or by prior calibration in a neutron field. The advantages of this method include: it is real-time; it can be used for small and large neutron fluxes; it can be designed for thermal and fast neutron flux measurements; and it is more accurate than SPNDs.⁶ The disadvantages include: it is more delicate; it can require a larger space in the reactor; and it requires signal leads from the experiment to outside the reactor.

2.1.3.1. Miniature and Sub-Miniature Fission Chambers

Irradiations at US MTRs are typically performed at high fluxes using small samples with limited space for instrumentation. In addition, some DOE-NE irradiations must be performed at high temperatures. Fission chambers must be sufficiently robust to survive these harsh conditions for the length of the experiment. As

such, special fission chambers have been developed or are under development for use in US MTR experiments. The following section discusses several of these in-core fission chambers deemed most promising.

The Commissariat à l'Énergie Atomique et aux Energies Alternatives (CEA) has over 40 years of experience in design, construction and use of miniature and sub-miniature fission chambers for MTR experiments (Figure 4).^{7,8} CEA-developed fission chambers are as small as 1.5 mm diameter for sub-miniature fission chambers and 3 mm diameter for miniature fission chambers. The designs utilize two coaxial cylindrical electrodes of which the center electrode is covered with fissile material. The area between the electrodes is filled with argon gas between 1-10 atm pressure. The complexity of the coaxial design along with the potential for the high pressure fill gas to leak makes these miniature fission chambers susceptible to damage during harsh irradiations.^{7,8} The CEA fission chamber sensitivity to thermal and fast neutrons is increased by using different fissile material deposits. In addition, as part of the Joint Instrumentation Laboratory, CEA and Studiecentrum voor Kernenergie Centre d'Étude de l'Énergie Nucléaire (SCK•CEN) have also developed a Fast Neutron Detector System (FNDS) for monitoring fast neutron flux in large flux environments. Prior to the development of a new type of fission chamber, CEA models the expected response with specially developed software.^{7,8}

Figure 4. Representative CEA miniature fission chambers and component sketch

2.1.3.2. Micro-Pocket Fission Detector Technology

Within the last decade, efforts were initiated by the Kansas State University (KSU) to develop the MPFD technology that has the potential to simultaneously detect thermal and fast flux along with temperature in a single miniature sensor.^{9 through 14} Initial 'proof-of-concept' evaluations to demonstrate MPFD technology performance were completed at the KSU TRIGA reactor. However, prior to deployment of this new MPFD technology in a US MTR, a more robust sensor design was required. As discussed in Section 3, previous

research conducted through NEET ASI¹⁻³ has shown that the MPFD technology could be made robust and was successfully tested in a reactor core.

MPFD technology utilizes the same concept as coaxial fission chambers, but with a different geometry that uses parallel electrodes instead of coaxial cylinders. This design is similar to a parallel plate ionization chamber with a neutron sensitive coating. However, the MPFD design is distinguished from other fission chambers because their signal is not based on the full energy deposition in the electrode gap from the fission products. This departure from conventional fission chamber design and operating characteristics allows the MPFD technology to have a much smaller chamber size with a much lower fill gas pressure. The MPFD design has excellent discrimination characteristics because the energy deposited by the fission products is much greater than other types of background radiation interactions in the detector. Another benefit is that the small size allows them to have a faster response time. Thus, the smaller MPFD design has the potential to achieve higher count rates than conventional fission chamber designs. The construction materials chosen for the MPFD technology includes temperature and radiation resistant ceramics. All of these characteristics make the MPFD technology well-suited to survive the harsh conditions present in DOE-NE MTR experiments.^{9 through 14}

3. MPFD INVESTIGATIONS

This section presents the scope for this NEET ASI project and summarizes investigation activities completed in this effort. A brief review of collaborator facilities and prior NEET ASI¹⁻³ activities to develop the MPFD technology is also presented. In addition, a discussion of irradiation deployment opportunities funded by other DOE-NE irradiation testing programs is included.

3.1. Overall Plan and Schedule

This joint INL/KSU/CEA project consists of seven tasks to be completed within three years. Figure 5 illustrates activities to be performed each year of this project and the organizations participating in each activity. Task 1 of this project is devoted to enhancing the previously developed MPFD design¹⁻³ for higher temperature applications and procuring candidate materials. Task 2 activities included refining construction techniques to fabricate a HT MPFD. Task 3 will evaluate the HT MPFD in high temperature furnaces and autoclaves as well as develop computer based analysis models of the detector performance. Task 4 will focus on evaluations in available irradiation facilities. In Task 5, investigators will procure new materials and refine the HT MPFD design and construction methods as well as update analysis models as needed depending on Task 4 results. Task 6 will repeat Task 4 evaluations and compare and contrast design changes in actual and analytical evaluations. Task 7 includes all of the ongoing reporting and project management to manage subcontracts and prepare annual reports and publications.

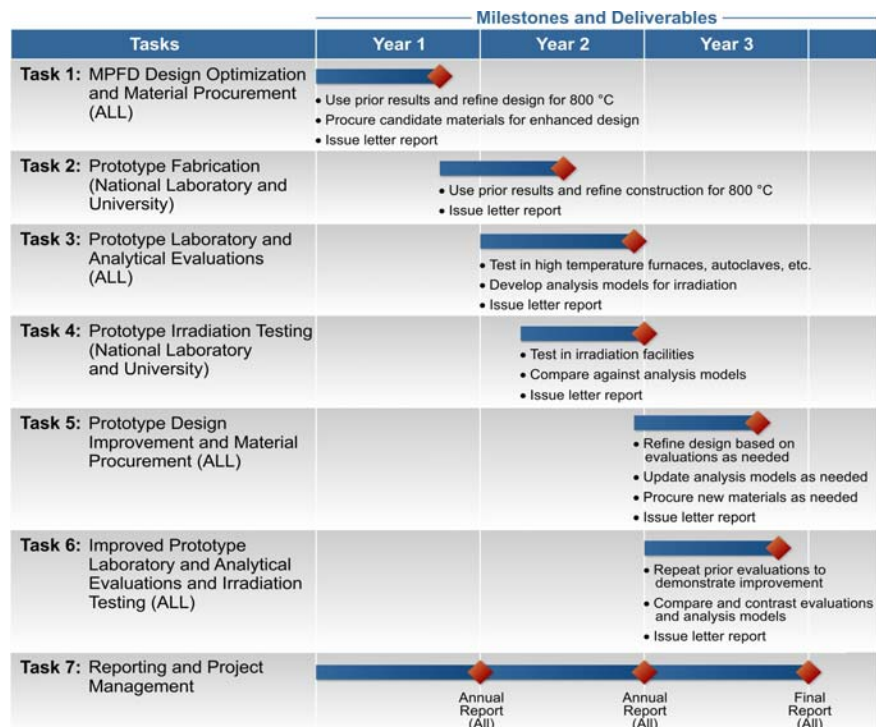

Figure 5. MPFD development tasks

3.2. Prior Activities and Capabilities

Research activities for previous development of the MPFD technology are discussed in the following sections. In addition, the capabilities of the collaborating organizations are summarized to provide a brief overview as why the research team was chosen.

3.2.1. Prior KSU MPFD Design and Evaluation Activities

Initial development of prototype KSU MPFD designs began in the early 2000's at KSU using large (~25 mm x 25 mm) alumina substrates with deposited electrical contacts (Figure 6).^{9 through 14} Evaluations for depositing neutron reactive materials explored various methods, including boron with physical vapor deposition, uranyl nitrate solution with an eyedropper, and uranium and thorium coatings using electrolysis. After the neutron reactive material was applied, the detector substrates were bonded together using epoxy in an argon atmosphere. Initial KSU MPFD prototypes were tested in a neutron beam at the KSU TRIGA research reactor with successful results. However, it was recognized that the manufacturing process was not ideal to produce detectors for in-core applications.

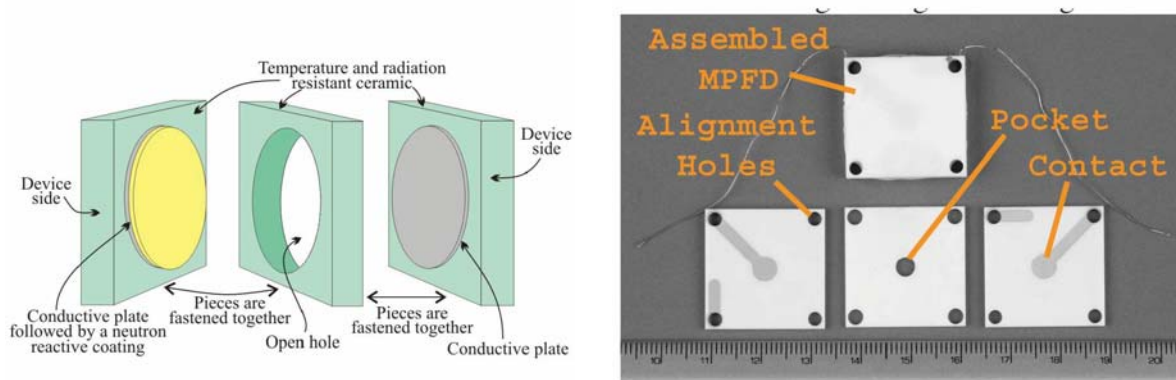

Figure 6. KSU MPFD component sketch (left) and initial KSU prototype MPFD (right)

The following years lead to further refinements of the KSU MPFD design that combined three chambers (one fast, one thermal, one background) and provided space for a thermocouple on a single substrate. Although the three chamber design incorporated multiple sensors in a single package, the new design was smaller (~25 mm x 6 mm) than previous designs.^{9 through 14} Electroplating proved to be the most reliable method to deposit the neutron reactive materials. Uranium was used for thermal neutron detection, and thorium was used for fast neutron detection. The background chamber was added to demonstrate that the neutron sensitive chambers were insensitive to background radiation. The provision for a temperature measurement with a Type K thermocouple wire bonded to the detector substrate was included; however, the attachment method was not ideal for optimal thermocouple performance.

Deployment of KSU MPFDs in their TRIGA reactor had limited success.^{9 through 14} The testing resulted in the largest amount of the MPFD technology ever installed in a reactor core, 225 detectors. However, only about one third of them functioned; and the detectors that did function had issues with cross-talk between the output signals. The operational issues were due to water flooding into the probe tubes, wiring isolation

issues, and improperly selected electronics. The probe tubes were constructed using three different diameters of aluminum tubes welded together using a TIG welder. The tubes were checked for leak tightness in a shallow water tank, but several tubes leaked when deployed in the KSU TRIGA reactor tank.

The wiring was required to exit the KSU designed MPFD perpendicular to the substrate and immediately make a 90 degree bend to travel inside a protective metal sheath. The wires were separated from each other using wire guides, but were not shielded from each other for their entire length. After deployment in the reactor, it was discovered that several of the wires were in contact with each other and the outer sheath, rendering many detectors unusable.

In addition, the KSU designed MPFDs utilized a single power source to reduce the amount of wires extending the length down to the reactor core. After deployment, it was determined that this arrangement introduced cross-talk issues that led to multiple pulses from a single detector that shared a power supply with other detectors.^{9 through 14}

3.2.2. Prior NEET ASI MPFD Design and Evaluation Activities

The MPFD technology gained interest for further development during a 3 year project to refine previous MPFD designs for use in MTR irradiations. A NEET ASI project, *Micro-Pocket Fission Detector*, was awarded in 2012 to develop a MPFD design suitable for use in these harsh irradiation conditions.¹⁻³

This MPFD design for MTR irradiations uses a round stackable geometry (Figure 7). The round design characteristic solves three problems associated with the previous KSU design. First, a round geometry is more suitable for installation in leak-tight swaged, drawn, or loose assembly tubes, eliminating water ingress problems. Second, the round tube geometry includes insulation for the wires along their entire length from the reactor core to the data acquisition system, eliminating the potential for wire-to-wire contact. Third, the wire connections are made through the detector substrate, eliminating a 90 degree wire bend used in the original KSU MPFD design (Figure 8).

Figure 7. Round geometry MPFD design suitable for MTR irradiations

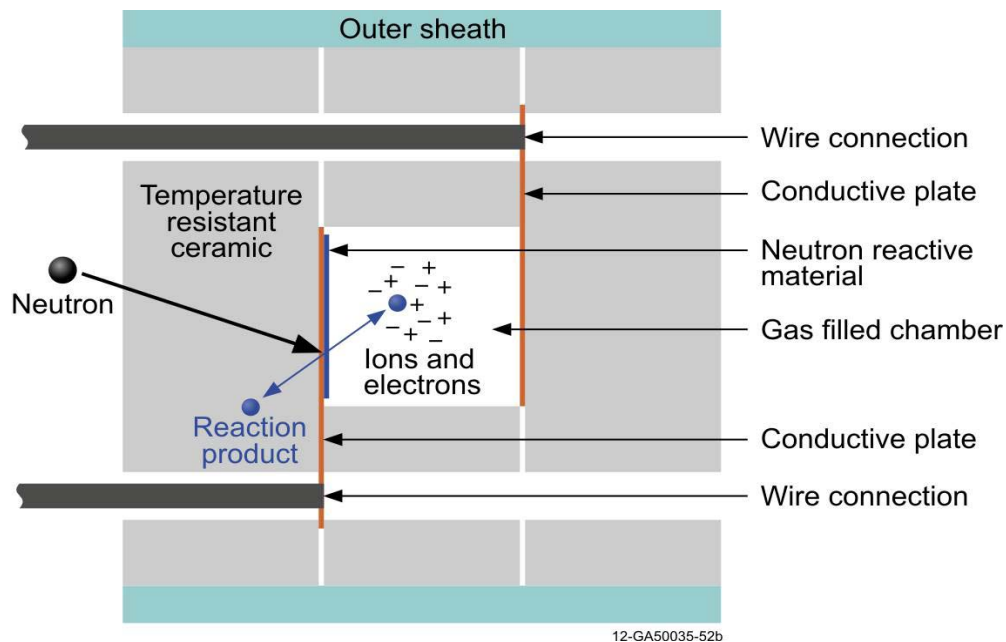

Figure 8. Component diagram of MPFD design showing wire locations

It was also determined that the third chamber used for detection of background radiation was unnecessary because prior KSU testing demonstrated the MPFD design is background insensitive due to the small size. An additional benefit of the stackable design is the potential for multiple detectors of varying sensitivities to be added as customer requirements dictate. The thermocouple is placed directly above the fission chambers in the loose assembly (Figure 9). This eliminates the additional wire bonding required in the KSU design, thus improving thermocouple performance and robustness. These improvements lead to an INL invention disclosure record to be filed on the MPFD technology.¹⁵

While undergoing redesign, the fabrication methods were assessed by considering thermocouple response, x-ray observations, helium leak checks, and resistance and continuity measurements. The material deposition was carefully monitored to produce robust electrical contacts and fissile material deposits. Sheath and weld integrity was evaluated using helium leak testing equipment to verify that the assembly meets requirements for the ASTM leak rate of mineral insulated thermocouples because that is the most analogous test for this unique sensor.¹⁶ Leak testing revealed that the round geometry MPFD leak rates were well below the acceptable ASTM leak rate limits.

After an acceptable leak rate was verified, external wiring was added to allow the round-geometry MPFDs to be connected to a data acquisition system (Figure 11) for long duration tests in a high temperature furnace. These evaluations were performed in furnaces to verify the internal wiring connections and thermocouple performance would survive at 500 °C for 1000 continuous hours. The evaluations indicated the wiring connections and thermocouple performance could survive at these elevated temperature for more than 1000 hours. As shown in Figure 12, the thermocouple inside this design of MPFD continued to provide a temperature reading consistent with the Type K reference thermocouple included in this test. Likewise, connections to flux detector components survived as indicated by their continuous and consistent voltage signal throughout the test.

Figure 9. Initial MPFD design for MTR irradiations

Figure 10. Leak testing an enhanced MPFD in specialized HTTL leak detection system

Figure 11. Round geometry MPFD installation into furnace and data acquisition system

Figure 12. Round geometry MPFD long duration high temperature test results

Radiation sensitivity testing was performed at the KSU TRIGA reactor by installing the round geometry MPFDs in the central thimble of the reactor core (see Figure 13) using KSU's specially developed signal amplifiers. The round geometry MPFDs were tested in-core at thermal and fast fluxes of $2.00 \times 10^{13} \text{ n/cm}^2\text{-s}$ and $2.00 \times 10^{14} \text{ n/cm}^2\text{-s}$, respectively. Typical detector pulses are shown in Figure 14.

Figure 13. MPFD installation in the central thimble at KSU TRIGA reactor

Figure 14. MPFD pulses during KSU TRIGA reactor testing

As this section demonstrates, the previous NEET ASI project demonstrated the potential of a new sensor that offers US MTR users enhanced capabilities for real-time measurement of the thermal and fast flux and of temperature with a single, miniature detector. These accomplishments have attracted funding for MPFD deployments from several DOE-NE irradiation testing programs as discussed in section 3.3.6.

3.2.3. KSU Research Facilities

KSU experience in producing the initial MPFD prototypes was beneficial for producing updated versions of neutron detectors that utilize the MPFD technology. KSU has several specialized laboratories to aid in the construction and testing of various radiation detectors.¹⁷ through ¹⁹ KSU specialties in the fabrication and implementation of the MPFD technologies include: building, testing, and optimizing detector amplifier boards for the MPFD technology; innovative fissile deposition for the MPFD technology; and evaluating the detectors at low fluxes in their nuclear reactor. This section summarizes KSU capabilities utilized for this effort.

3.2.3.1. SMART Laboratory

The Semiconductor Materials and Radiological Technologies (SMART) Laboratory at KSU is a unique facility dedicated to the research and development of new and innovative radiation detector technologies. The SMART Laboratory houses specialized equipment to support that work, including two clean rooms, a fission chamber plating station (Figure 15), a linear drive diamond cutting wheel, a diamond wire saw, precision lapping and polishing machines, a 6-pocket e-beam evaporator (Figure 16), an ion mill, a vacuum annealing chamber, microscopes, ovens, grinders, an assortment of furnaces for annealing, sintering, diffusions, and oxidations, a scanning electron microscope, an Auger electron analyzing system, IV and CV tracers, radiation sources, and NIM electronics to test and characterize radiation detectors and materials. The SMART Laboratory completed construction of its newest 1000 square foot class 100 clean room facility that has been fully operational as of March 2012.¹⁷

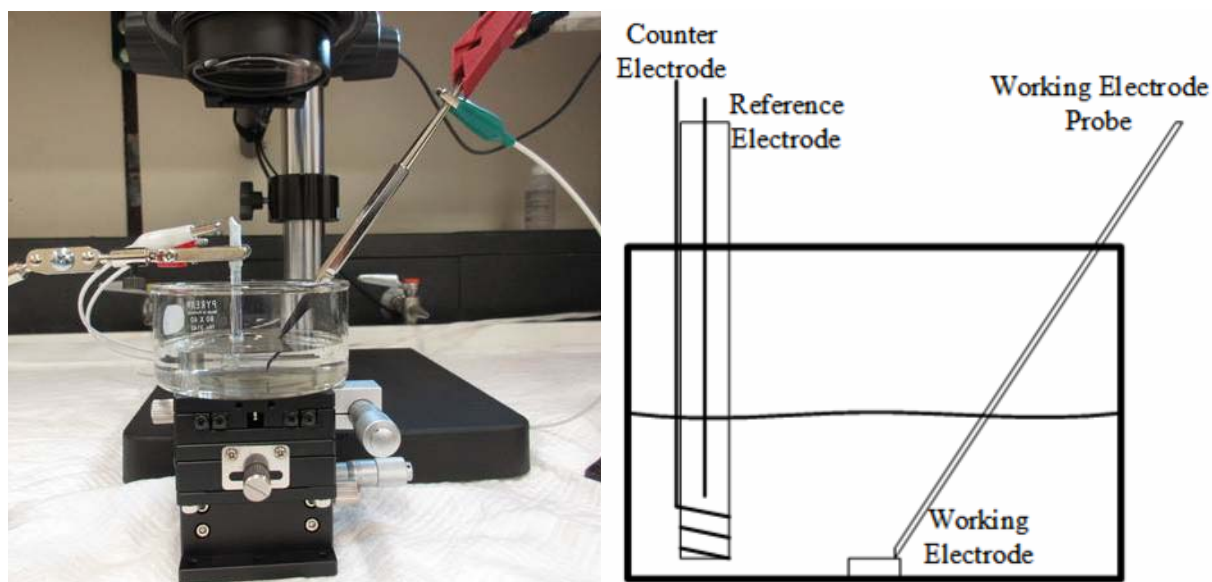

Figure 15. MPFD sample undergoing micro-electroplating of fissile material at the KSU SMART Laboratory

Figure 16. Electron-beam evaporator depositing material at the KSU SMART Laboratory

The facility is available to students and faculty for research and development of sensors. The SMART Laboratory serves as a center for undergraduate and graduate student education as well as a facility to accommodate funded research projects from various government and industrial sponsors.¹⁷

3.2.3.2. TRIGA Mark II Research Reactor

The TRIGA Mark II research reactor at KSU supports education, research, training, and regional industries. The reactor is used extensively by the SMART Laboratory for testing of radiation sensors and irradiation of materials. The KSU TRIGA is licenced to a 1.25 MW steady state operating power and has pulsing capabilities up to ~2 GW, making it ideally suited for testing new sensors in high-power transients. The peak steady-state thermal flux and fast flux available in-core are approximately 2.50×10^{13} n/cm²-s and 2.50×10^{14} n/cm²-s, respectively.¹⁸ Sensors can be tested from source range to full power in reactor beam ports or directly in the reactor core. In 2015, the Intra Reflector Irradiation System (IRIS) was installed in the reactor to aid in irradiations. IRIS is a system of in-core dry tubes that allows in-core sensor evaluations to be performed without a concern of water ingress as shown in Figure 17. The ease of access to this reactor facility makes it an asset to the SMART Laboratory for in-core neutron detector testing.¹⁸

3.2.3.3. Electronics Design Laboratory

The KSU Electronics Design Laboratory (EDL) works closely with the SMART Laboratory to develop and test the required electrical systems needed to support sensor research and development. EDL's focus is to provide researchers access to advanced electronics and assist with integrating electronics technology into research programs. EDL is an in-house design service for KSU researchers. The staff has both industry

Figure 17. KSU Intra Reflector Irradiation System (IRIS) (left) at KSU TRIGA reactor (right)

and research experience with analog instrumentation and digital design, as well as software development, system engineering, system construction, and project management.¹⁹

3.2.4. INL Research Facilities

The INL's role in developing the MPFD technology utilizes its experience in developing and deploying unique in-pile instrumentation suitable for irradiation testing programs that operate in high flux and high temperature conditions. This section summarizes INL capabilities utilized for this effort.

3.2.4.1. High Temperature Test Laboratory

INL has several specialized facilities to construct and test high performance instrumentation. The High Temperature Test Laboratory (HTTL) contains specialized equipment to design advanced in-pile sensors and conduct high-temperature testing. HTTL's trained staff evaluates high-temperature material properties and develops custom high-temperature instrumentation for nuclear and non-nuclear applications, including new methods for measuring temperature, thermal conductivity, localized heating, and sample deformation in MTRs. In addition, the HTTL houses specialized equipment to support such work, including high-temperature tube furnaces, a high-temperature vacuum furnace, swagers, a draw bench, two laser welders, an electron beam welder, a helium leak detector system, a real time X-ray imaging system, a 3D computed tomography (CT) system, several autoclaves, and various high-temperature material property measurement systems (see Figure 18). HTTL efforts support DOE-NE irradiation testing programs that require specialized in-pile sensors for fuels and materials irradiations.²⁰

In 2014, the HTTL was relocated to a new state-of-the-art facility at INL, the Energy Innovation Laboratory (EIL) (see Figure 18). The inclusion of a clean room capability and additional new state-of-the-art equipment including the 3D CT system, fiber laser welder, and electron beam welder furthers HTTL's role as a world-class in-pile instrumentation development and testing facility.²¹

Figure 18. HTTL layout in INL's Energy Innovation Laboratory

INL capabilities also include a unique facility for testing in neutron fields, the ATR Critical facility (ATRC). A brief description of this facility is provided below. In addition, calibration activities performed at the ATRC related to flux detection are presented.

3.2.4.2. ATRC Facility

The ATRC core is a nearly-identical full-scale nuclear mock-up of the ATR core and can provide valuable insight into the use of advanced sensors prior to deployment in the ATR. The current mission of the ATRC is to obtain accurate and timely data on nuclear characteristics of the ATR core, such as rod worths and calibrations, excess reactivities, neutron flux distribution, gamma-heat generation rates, fuel loading requirements, and effects of the insertion and removal of experiments. The ATRC provides a necessary supplement to analytical reactor methods that support ATR operation. Although the ATRC typically operates at power levels of 600 watts or less, its authorized maximum power level is 5 kW. The core power is maintained at low levels to minimize radiation exposures during manual operations required to unload experiments and fuel. As discussed in section 3.2.4.3, an NSUF project has developed and installed Experiment Guide Tubes (EGTs) into ATRC irradiation positions (Figure 19). This specialized fixturing provides INL a unique capability for comparison evaluations of real-time neutron flux detectors.²²

3.2.4.3. Flux Detector Calibration Facility at ATRC

As noted in Section 3.2.4.2, ATRC research funded by an ATR NSUF program has resulted in neutron detector evaluation capabilities at INL that are beneficial to HT MPFD development. The project, a joint Idaho State University (ISU)/CEA/INL collaboration, was initiated to investigate the feasibility of using neutron sensors to provide online measurements of the neutron flux and fission reaction rate in the ATRC. The project cross-calibrated various activation detectors (foils and wires), miniature fission chambers, SPNDs and back-to-back (BTB) fission chambers in the ATRC. The SPNDs under evaluation had hafnium, gadolinium and rhodium emitters for thermal neutron detection. The fission chambers under evaluation had U-235 fissile deposits for thermal neutron detection and U-238 fissile deposits for fast neutron detection. The in-core sensors were inserted into the ATRC using EGTs (Figure 19) and also installed in the northwest in-pile tubes.

Figure 19. In-core sensors installed in the ATRC

Detector evaluations were performed for a variety of operational conditions in 2013. The reactor was brought to specified power levels between 0.01W and 600W. In addition, measurements were taken with the reactor shut down prior to startup and with the reactor shut down after startup. In order to assess if the detectors could be used to monitor various power splits, the reactor was purposely operated in an unbalanced condition, meaning the reactor power in the NW lobe was purposely changed from the nominal critical power level.

Initially, the flux sensors were verified to be operational; then, the detectors were used to track reactor power. Typical data obtained from axial flux testing and power level testing is shown in Figure 20. In addition to data collection, various insights were gained during the testing of the in-core sensors related to

installation, operation, and data analysis. Additional details related to this testing are documented in References 23, 24 and 25.

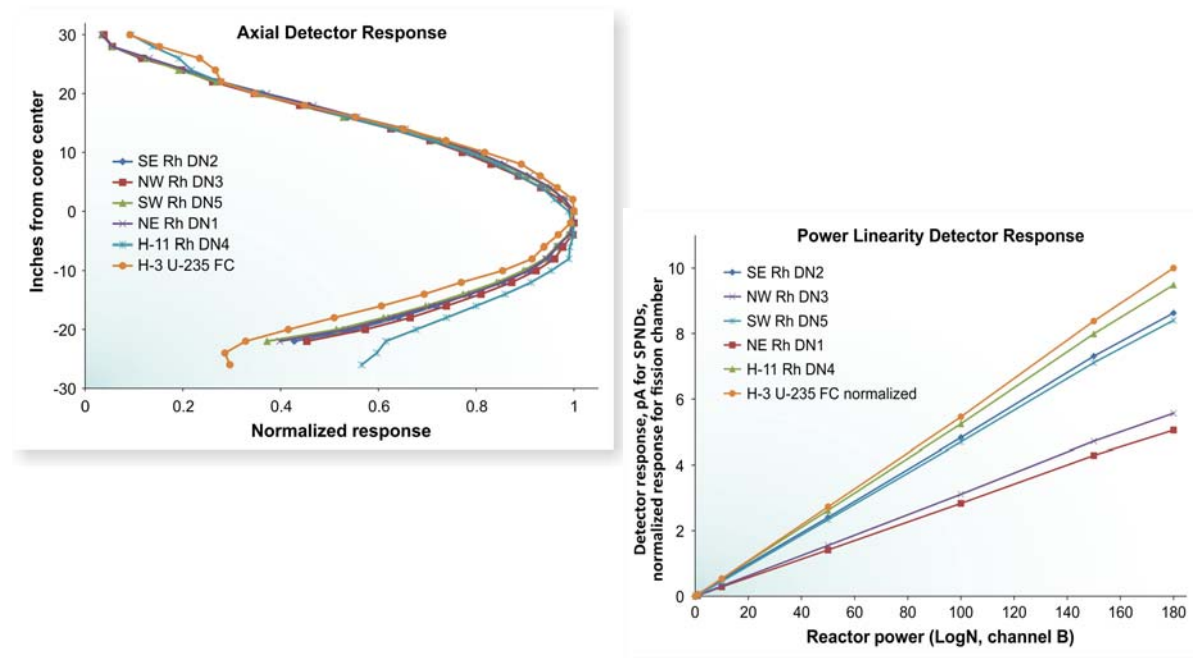

Figure 20. Axial flux profile (left) and power measurements (right) obtained from rhodium SPNDs and a fission chamber

Other cross-calibration fixtures for ATRC were tested in 2014. Specialized fixtures allowed a BTB fission chamber to be inserted into the ATRC. The BTB fission chambers, which are often called 2π fission chambers because they are designed to count almost all fission fragments emitting from a thin deposit in a 2π solid angle, provide the most accurate measure of fission reaction rates and provide accurate cross-calibrations of other detectors such as a HT MPFD. These fixtures place a BTB fission chamber in the ATRC core alongside other in-core sensors to compare their response in near-identical flux conditions. Further experimental details can be found in Reference 25 and current uses for the BTB fission chamber for calibration of HT MPFD fissile deposits is discussed in section 3.3.2.

3.2.5. CEA Contributions

The CEA has over 40 years of experience in design, construction and use of miniature and sub-miniature fission chambers for MTR experiments. The CEA has developed many specialised computed modeling codes to aid in fission chamber research and development. The CEA contribution to this project was to provide technical guidance and modeling capabilities as needed. Two meetings were held at INL in FY16 to discuss INL and CEA collaboration activities on advanced instrumentation (Figure 21). Both meetings discussed a wide variety of instrumentation including potential collaboration activities related to HT MPFD development.

Figure 21. INL/CEA November 2015 meeting (left) and June 2016 meeting (right)

3.3. Current HT MPFD Developments

Previous research conducted through NEET ASI¹⁻³ has shown that the MPFD technology could be made robust and was successfully tested in a reactor core. This project continues to further develop the MPFD technology for higher temperature regimes and other reactor applications. This HT MPFD will be developed, fabricated, and evaluated using techniques perfected by INL's HTTL staff during development of other high temperature in-pile sensors, equipment and knowledge possessed by KSU for material depositions and electronics design, and the expertise in miniature fission chamber design possessed by CEA.

3.3.1. FY17 Activities

The final year of this three year project focused on irradiation deployments and development of new research activities as well as commercialization activities for the HT MPFD. Irradiation deployment utilized the updated electrodeposition of fissile materials process that for consistent fissile material deposition.²⁹ The final detector geometry deployed moved from a parallel plate design to a parallel wire design as shown in Figure 22. This design update allows the MPFD to maintain the electric field in the gas region (Figure 23), but to be constructed without the need for the conductive adhesive as used in previous designs. Removal of the conductive adhesive eliminates the potential failure mechanism of a breakdown on the adhesive in a radiation field. This design change is a significant improvement in HT MPFD survivability in a long duration irradiation test.

Figure 22. HT MPFD parallel plate design (left) and parallel wire design (right)

Figure 23. HTMPFD parallel wire diagram

3.3.2. HT MPFD Fissile Material Deposition

The KSU SMARTLab is responsible for plating all coatings required for HT MPFD construction. Two plating steps are performed; the first step is to plate the electrical contacts or electrodes on the alumina substrates. The second plating step is to deposit the fissile material on one of the electrical contacts.

The initial plating to deposit the electrical contacts is performed using an electron-beam evaporator (Figure 16). The plating requires custom shadow masks for the HT MPFDs to be machined using a micro-milling machine at KSU. The purpose of the shadow masks is to selectively deposit the contact material that defines the electrical contacts and wire-bonding pad. Titanium and platinum are used as the contact materials. A thin layer of titanium is used to attached to the alumina, then a thicker layer of platinum is used for the electrical contact and to provide a basis for the fissile material electroplating.

Once the electrical contacts are in place, the second plating step will deposit the material. Natural uranium is used for thermal neutron detection and natural thorium is used for fast neutron detection, but other fissile materials could be deposited to alter signal response as requested by irradiation programs. Standard micro-electroplating methods are used to deposit the fissile materials. The small substrates and thin depositions utilize a specialized nA-current electrodeposition system at KSU (Figure 24).^{29,30}

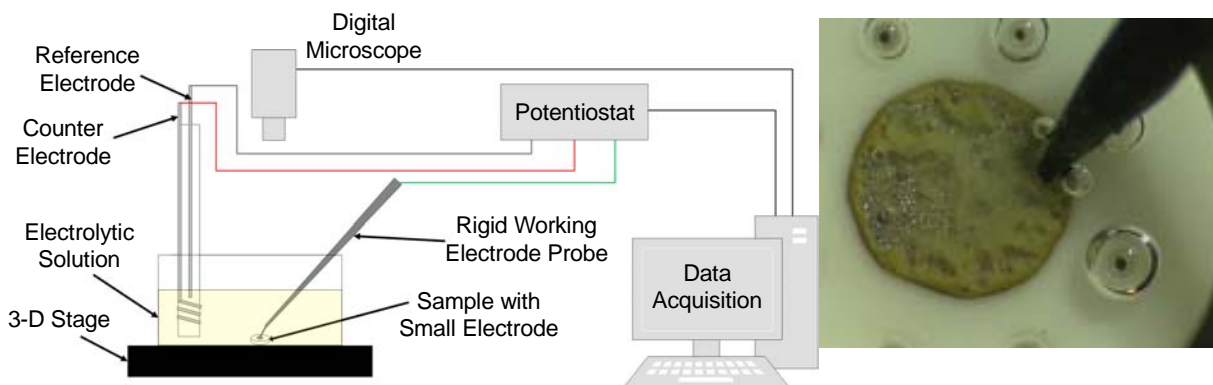

Figure 24. Electrodeposition system at KSU (left) with HT MPFD under deposition (right)

Contact deposition quality has been verified by using KSU's optical profilometer, x-ray fluorescence analyzer (XRF) (Figure 25), scan electron microscope (SEM), and electrochemical analyzer. In addition, the fissile deposit characterization is completed by using a specialized 2π solid angle gas detector to verify the amount of material deposited is consistent with predictions.³¹

Figure 25. Electrodeposited sample of uranium under analysis with XRF

Addition independent verification of the fission material is under investigation at INL using a 3D laser scanning confocal microscope. Initial investigations of the MPFD surface finish are shown in Figure 26.

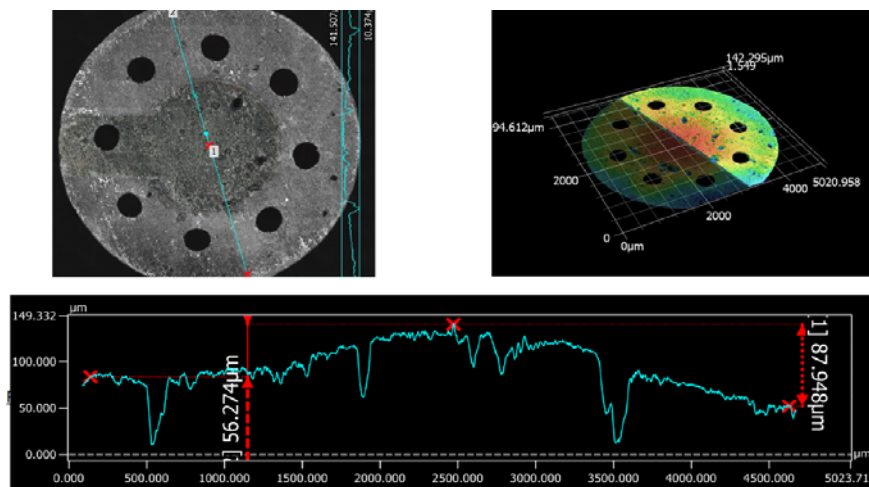

Figure 26. Surface profile of HT MPFD using 3-D laser scanning confocal microscope

The TREAT IRP is also funding independent characterization of KSU's fissile material deposition process used in the fabrication of HT MPFDs. Initial investigations have focused on cross-calibrations against the BTB fission chamber fissile material depositions to verify the fissionable deposit mass measurements performed at KSU, and to further decrease the uncertainty of the measurements. These investigations are being performed at the Idaho State University Reactor Laboratory using the AGN-201 reactor with specially developed BTB fission chambers as shown in Figure 27.

Figure 27. BTB fission chamber (left) and fissile material characterization at the Idaho State University Reactor Laboratory (right)

3.3.3. HT MPFD Amplifier Electronics

The EDL at KSU had designed previous versions of amplifier electronics in support of MPFD deployments, however it was recognized that a more complex amplifier system was needed for future deployments so Mesytect was contacted to develop a 4 channel readout in support of future MPFD deployments. Initial V1.0 MPFD electronics have been tested with MPFDs at the KSU TRIGA to demonstrate proof of

concept. Further refinements were added to develop an updated system as shown in Figure 28. The new electronics design consist of a humidity resistant pre-amplifier box that interfaces directly with a NIM processing module. The system includes charge sensitive preamplifiers, a HV bias supply, a filter stage and associated discriminators. All adjustments and data can be controlled and transmitted via USB interface. The electronics will output up to 4 discriminator signals for an external counter. This system is available directly from Mesytec and has been deployed at the ATR, MITR, MINERVE, and several TRIGA reactors.

Figure 28. Mesytec electronics system under operation at the MIT Reactor Laboratory

3.3.4. HT MPFD Fabrication

The HTTL's expertise in robust sensors for MTR irradiations was used to improve the design for the HT MPFD. Using this expertise, the round, stackable geometry that is more suitable for installation in a leak-tight tube and that has improved thermocouple connections and wiring transitions was maintained. Careful material selection should allow the HT MPFD to be capable of operating at temperatures up to 800 °C.

The main components of the HT MPFD detector and extension cable are specially manufactured hard-fired ultra smooth alumina substrates and crushable alumina insulators (Figure 29), respectively, all housed within leak-tight tubing. The outer sheath was changed from the stainless steel that was used in previous MPFD designs to Inconel for improved survivability in high temperatures and in harsh irradiation conditions. Wiring and tube-to-tube transitions use specially machined Inconel adapters that position the tubes uniformly for welding repeatedly. In addition, a tube cap was specially machined for the loose assembly tube for a tight fit. A "loose assembly construction" was used with a rigid Inconel tube for the active area of the sensor (Figure 29). Modeling has shown that a wall thickness of 0.020" will allow the integrity of the sheath to survive in accident conditions up to 9000psi as required for transient irradiation testing. This tube contains hard-fired alumina substrates for the fission chamber electrodes and the fissile depositions and wire contacts. The crushable alumina insulators serve as an insulator for the six wire extension cable that also utilizes an Inconel outer sheath. In addition, the HT MPFD design moves the thermocouple to the extension cable to improve thermocouple response.

Figure 29. Spacer for parallel wire HT MPFD design (left) and loose assembly of HT MPFD (right)

The HT MPFD prototype was analyzed using HTTL's 2D X-ray system to verify thermocouple placement in the extension wires prior to final assembly (Figure 30). After assembly was complete, a more detailed micro focus 3D CT scan was completed at the HTTL to verify integrity of the welds on the outer sheath (Figure 31). This scan was also used to identify accurate placement of the internal features of the HT MPFD prior to deployment.

Figure 30. HT MPFD thermocouple placement in extension cable (left) and final assembly (right).

Figure 31. HT MPFD 3D CT scans with varying contrast ratios to identify internal features.

This design was used to construct HT MPFDs for irradiation testing deployments in ATR and MITR as discussed in section 3.3.6 and shown in Figure 32. Other deployments in MINERVE and TRIGA reactors used a similar design, but did not include the specially manufactured extension cable to allow for assembly without a laser welder.

Figure 32. Laser welding (before/after) of HT MPFD at HTTL for ATR and MITR deployments

3.3.5. HT MPFD Modeling for TREAT

Testing of experimental fuel in accident conditions is an important step in qualifying new reactor fuels and determining the safe operating conditions for advanced reactor designs. HT MPFDs will be deployed along with other advanced instrumentation in the multi-Static Environment Rodlet Transient Test Apparatus (SERTTA) vehicle in the central test channel in the TREAT reactor as shown in Figure 33. The current HT MPFD design for tests at the TREAT facility was modeled in MCNP and tested in the expected neutron flux profile. The MPFD sensitivities for ^{242}Pu , ^{232}Th , natural uranium, and 93% enriched ^{235}U were calculated and reported for the TREAT neutron flux profile. These results show that the expected interaction rate of the fissile coating of an MPFD during peak flux levels of a TREAT pulse will exceed the operational range of traditional pulse-mode operation. Subsequently, current-mode electronics are being developed for transient testing of MPFDs. The variation of electrode thickness, active material thickness, and material were all examined. The parameters for the current MPFD design were found to have no negative effects on the operation of the sensor nor on the neutron flux in the vicinity of the experimental assembly.

3.3.6. HT MPFD Deployments and Additional Research Activities

As previously stated, sensors developed for NEET ASI projects should strive to meet irradiation testing program needs. Two MTR irradiation programs have recognized the value of the NEET-developed HT MPFD technology and are independently funding deployments of HT MPFDs. These are significant opportunities for the FY15-FY17 *NEET Enhanced Micro-Pocket Fission Detector for High Temperature Reactors* project because the expense of these irradiations could not be included in the original project scope.

Figure 33. MCNP Transient-MPFD model (left) and location in experiment (right)

3.3.6.1. AGR 5/6/7 Irradiation

The NGNP program is pursuing evaluations of a suite of advanced real-time in-core sensors during their 3 year test campaign in the ATR. The AGR 5/6/7 irradiation program is funding the sensor procurement, data acquisition system and engineering effort required to integrate sensors into the test train. The suite of instrumentations includes:

- 1 Ultrasonic Thermometer (NEET-developed sensor)
- 1 Micro-Pocket Fission Detector (NEET-developed sensor)
- 3 Self Powered Neutron Detectors
- 1 Fiber Optic Temperature Sensor
- 1 Ionization chamber

The program will use the HT MPFD design (Figure 22), but has requested a change from a Type K to a Type N thermocouple to match the other thermocouples installed in the test. Both the NEET-developed sensors and the other sensors in these evaluations will be tested at unprecedented flux levels by leveraging the AGR 5/6/7 irradiation program. This evaluation will further demonstrate the usefulness of the MPFD to simultaneously measure fast flux, thermal flux and temperature in a typical ATR long duration irradiation test.

Activities completed in FY17 include installation of the HT MPFD in the test train as shown in Figure 34. This irradiation is scheduled to be started in the first quarter for FY18.

3.3.6.2. Accident Tolerant Fuels

The Accident Tolerant Fuels (ATF) program is deploying an HT MPFD in the ATF-2 sensor qualification test to evaluate a suite of advanced sensors, including the NEET-developed HT MPFD. The ATF-2 irradiation program funded the construction, installation (Figure 35) and testing of a MPFD (along with other advanced sensors) during these irradiations. This irradiation will evaluate a HT MPFD in the ATR during a single operation cycle, approximately 59 days, scheduled to be started in the first quarter of FY18.

Figure 34. AGR 5/6/7 test train (left) and MPFD cabling (right)

Figure 35. HT MPFD assembly and wiring for ATF-2 sensor qualification test

Additional work related to the ATF programs will include a additional irradiations to evaluate a specialized version of the MPFD technology that is suitable for reactor transients. This version is currently being developed though the TREAT Baseline Instrumentation Development program for use by operations and experiments.³³ This version of the MPFD is scheduled to be installed in the multi-SERTTA as shown in Figure 36 and Figure 37 to aid in the monitoring of experiment transients.³² This effort will be a departure from previous MPFD designs because the focus will be on developing a robust, fast response MPFD that has two low efficiency and two high efficiency neutron detectors and does not include a thermocouple as shown in Figure 38.

Research is underway to characterize the fissile material behavior throughout a reactor transient. The high power that is deposited in the fission chamber has been modeled and experimental analyzed by KSU. As shown in Figure 39, the fissile deposit is undergoing a physical change and investigations are continuing to understand how this will effect detector performance.³³

A United States-Republic of Korea (US-ROK) International Nuclear Energy Research Initiative (INERI) project was awarded in FY17 titled, *Radiation Hardened Readout Circuit Design for High Temperature Micro-Pocket Fission Detectors Operating in Harsh Environments*. This collaboration will develop radiation hardened electronics to aid in deployment of HT MPFD for irradiation tests and well as to support

Figure 36. Sensor locations near the fuel specimen in the Multi-SERTTA irradiation test vehicle for ATF-3; MPFD shown in purple

Figure 37. Overall layout of the Multi-SERTTA irradiation test vehicle for ATF-3; MPFD shown in purple on right

future deployments that may require electronics that can survive accident conditions. As shown in Figure 40, the circuit design has been completed and a kick-off meeting was held at INL.³⁴

An MPFD was deployed at the CEA MINERVE zero power physics reactor as part of an INL/CEA summer internship. The deployment focused on developing a characterization strategy for the MPFD by using the methods developed for CEA miniature fission chambers. This strategy utilizes accurate measurement of the fissile material for input into computer simulations that are validated with experimental data from the well-characterized irradiation channels in MINERVE. As shown in Figure 41, the MPFD was successfully tested in the MINERVE reactor and the data is current being evaluated and will be published when completed.

Figure 40. Radiation hardened pre-amplifier design (left) and kickoff meeting at INL (right)

Figure 41. MPFD pulse from MINERVE reactor deployment

In addition to these INL-led deployment activities, several Nuclear Energy University Program (NEUP) research and development projects will leverage the MPFD technology for a variety of experiments. The Nuclear Energy Advanced Modeling and Simulation (NEAMS) project, *A Transient Reactor Physics Experiment with High Fidelity 3-D Flux Measurements for Verification and Validation* will use MPFDs for measurement of real-time reactor fluxes for validation of detailed computational models of the University of Wisconsin-Madison research reactor.²⁷ As discussed in section 3.3.2, the Integrated Research Project (IRP), *Advanced Instrumentation for Transient Reactor Testing* is working to develop fissile material characterization methods to aid characterization efforts of MPFDs. Another IRP, *Computational & Experimental Benchmarking for Transient Fuel Testing* has tested an HT MPFD with other advanced instrumentation in the MIT Reactor (Figure 28) for comparative testing of in-core instrumentation for future deployment in TREAT.

The success of the MPFD technology has attracted interest from a commercialization partner that was awarded a Small Business Innovative Research (SBIR) Phase I project in FY17 titled, *Advanced Manufac-*

turing of Micro-Pocket Fission Detectors. This project, lead by Radiation Detection Technologies (RDT), is underway to develop a commercialization strategy that utilizes advanced manufacturing techniques to further refine the design for larger deployments that require a high volume of MPFDs. After the Phase 1 feasibility and proof of concept study is completed, RDT will apply for a Phase II project to continue the R&D for a MPFD prototype that will lead to a commercialized MPFD.³⁵

4. SUMMARY

All project objectives were met and all planned activities were completed. The joint work between INL, KSU, and CEA produced a HT MPFD design with supporting materials, equipment, and electronics.

The development, testing and analysis completed in this project has provided the necessary information to demonstrate the viability of HT MPFDs for irradiation testing programs. This new sensor has or is expected to be deployed in ATR, TREAT, MITR, MINERVE and TRIGA reactors as well as the subject of a SBIR project. Test reactor users now have a capability for real-time measurement of the thermal and fast flux and of temperature with a single, miniature detector. This section summarizes the objectives, accomplishments, importance, and future work of this NEET ASI project.

4.1. Project Objectives

The project objectives were carefully chosen to develop a sensor that will significantly advance flux detection capabilities for irradiation tests in US MTRs. The objectives, which were all successfully completed within this three year project, include:

- Project meetings at KSU and INL.
- Refine MPFD design for high temperatures up to 800 °C.
- Refine fissile material deposition system and methods for HT MPFD fissile deposition.
- Select and procure quality approved materials for HT MPFD deployments.
- Construct and analyze HT MPFD using new materials, methods and equipment.
- Refine amplifier design to improve HT MPFD performance for irradiation testing deployments.
- Complete fissile material characterization activities.
- Complete modeling of the HT MPFD to support fabrication activities for HT MPFD deployments.
- Interface with various DOE-NE irradiation testing programs deploying HT MPFDs.
- Submit final project report and publications on MPFD developments and evaluations

4.2. Accomplishments

The research, development, testing and analysis in this project has developed a robust sensor for DOE-NE irradiation testing programs. Highlights from research accomplishments include:

- A joint collaboration was initiated between INL, KSU, and CEA. Note that CEA is participating at their own expense because of interest in this unique new sensor.
- Several project meetings were held at INL and KSU to discuss the roles and responsibilities between INL, KSU, and CEA for development and deployment of the HT MPFDs.
- An updated HT MPFD design was developed.
- Selected and procured new high temperature compatible materials for HT MPFD prototype construction.
- Construction methods to support the new design were evaluated.
- Performed laboratory evaluations of construction methods of prototype HT MPFD.
- Electrical contact and fissile material plating performed.
- Updated detector electronics evaluations completed.
- Publications of MPFD technology accepted.
- Program support for HT MPFD deployments was given to Accident Tolerant Fuels (ATF) and Advanced Gas-cooled Reactor (AGR) irradiation test programs.

- An updated parallel wire HT MPFD design was developed.
- Quality approved materials for HT MPFD construction were procured by irradiation test programs for HT MPFD deployments.
- KSU improved and performed electrical contact and fissile material plating.
- KSU delivered fissile HT MPFD parts to INL for final construction of HT MPFD prototype.
- A prototype HT MPFD was constructed and analyzed at INL.
- The HT MPFD has been modeled in MCNP to optimize the amount of fissile material deposition.
- The HT MPFD has been modeled in MCNP to optimize the sensor location in the irradiation test.
- Detector amplifier electronics have been revised and tested by KSU.
- HT MPFD fissile material deposition is undergoing independent verifications at the ISU AGN-201 reactor.
- HT MPFD deployed at the CEA MINERVE for characterization of detector response.
- HT MPFD deployed at the MIT Reactor for characterization of TREAT instrumentation.
- HT MPFD deployed in a the KSU TRIGA reactor.
- TH MPFD deployed in the UW TRIGA reactor.
- HT MPFD installed in irradiation test trains for AGR 5/6/7 and ATF-2.
- US-ROK INERI project awarded to develop radiation hardened electronics for HT MPFD.
- SBIR Phase 1 awarded to commercialize HT MPFDs.
- HT MPFD under construction for deployment in TREAT cooling channels.

As noted within this report, this the final year of a three year project. Future research will focus on irradiation testing deployments to evaluate the HT MPFD in a variety of testing conditions as part of other DOE-NE programs evaluating the performance of candidate new fuels and materials to better characterize irradiation test conditions.

4.3. Importance of Superior Flux Detector

When implemented, these sensors will significantly advance flux detection capabilities for irradiation tests in US MTRs. Specifically, deployment of HT MPFDs will address several challenges faced in irradiations performed at MTRs:

- Current fission chamber technologies do not offer the ability to measure fast flux, thermal flux, and temperature within a single compact probe; HT MPFDs offer this option.
- HT MPFD construction is very different than current fission chamber construction; the use of high temperature materials and unique design characteristics allow HT MPFDs to be specifically tailored to survive harsh conditions encountered in high performance MTR irradiation tests.
- The higher accuracy, high fidelity data available from the compact HT MPFD will significantly enhance efforts to validate new high-fidelity reactor physics codes and new multi-scale, multi-physics codes.
- HT MPFDs can be built with variable sensitivities to survive the lifetime of an experiment or fuel assembly in some MTRs, allowing more efficient and cost effective power monitoring over a wide range of reactor powers.
- The small size of the MPFD technology allows multiple sensors to be deployed, offering the potential to accurately measure flux and temperature profiles in the reactor.

4.4. Future Research, Deployment and Commercialization Activities.

In addition to the development of the HT MPFD in this NEET ASI project, other DOE-NE irradiation testing programs and other nuclear research programs are deploying MPFDs in irradiation tests. These deployments demonstrate the importance of this NEET-developed technology and are significant opportunities for the HT MPFD because these irradiations could not be included in the original project scope.

The NGNP program has built a test train with advanced instrumentation, including a HT MPFD in the graphite in the top capsule of the AGR-5/6/7 fueled irradiation test. This evaluation, scheduled to be started in the first quarter for FY18, will further demonstrate the usefulness of the MPFD technology to simultaneously measure fast flux, thermal flux and temperature in a typical ATR long duration irradiation test.

The ATF program has built a test train to include the HT MPFD for the ATF-2 sensor qualification irradiation test. This irradiation will evaluate a HT MPFD in the ATR during a single operation cycle, approximately 59 days, scheduled to be started in the first quarter of FY18. The ATF-2 irradiation program funded the construction, installation and testing of a these HT MPFDs (along with other advanced sensors) for this irradiation. Additional work related to the ATF programs will include a second irradiation to evaluate a specialized version of the MPFD technology that is suitable for reactor transients. This version is being developed through the TREAT Baseline Instrumentation Development program for use by operations and experiments. Although the transient-specific MPFD will be different from the HT MPFD design, it is expected that the information gained in the irradiation of a transient-specific MPFD will aid in further refinement of the HT MPFD for survivability in accident conditions.³³

Additional research and deployment will be conducted through a variety of NEUP projects:

- The NEAMS project, *A Transient Reactor Physics Experiment with High Fidelity 3-D Flux Measurements for Verification and Validation* will use MPFDs for measurement of real-time reactor fluxes for validation of detailed computational models.²⁷
- The IRP, *Advanced Instrumentation for Transient Reactor Testing* is working to develop fissile material characterization methods to aid characterization efforts of MPFDs.
- The IRP, *Computational & Experimental Benchmarking for Transient Fuel Testing* has tested an HT MPFD with other advanced instrumentation in the MIT Reactor for comparative testing of in-core instrumentation for future deployment in TREAT.

An MPFD was deployed at the CEA MINERVE zero power physics reactor as part of an INL/CEA summer internship. The deployment focused on developing a characterization strategy for the MPFD by using the methods developed for CEA miniature fission chambers. This strategy utilizes accurate measurement of the fissile material for input into computer simulations that are validated with experimental data from the well-characterized irradiation channels in MINERVE.

The US-ROK INERI project, *Radiation Hardened Readout Circuit Design for High Temperature Micro-Pocket Fission Detectors Operating in Harsh Environments*, is developing radiation hardened electronics to aid in deployment of HT MPFD for irradiation tests and well as to support future deployments that may require electronics that can survive accident conditions.³⁴

The SBIR Phase I project, *Advanced Manufacturing of Micro-Pocket Fission Detectors*, lead by Radiation Detection Technologies, is underway to develop a commercialization strategy that utilizes advanced manufacturing techniques to further refine the design for larger deployments that require a high volume of MPFDs.³⁵
